At the monthly meeting of the committee of management of the Londonderry Lunatic Asylum on Jan. 19th a proposal came up to follow the precedent of County Donegal and County Tyrone and leave ample room in the existing asylum for the 139 city of Derry patients by providing accommodation for the 333 county patients in some of the almost empty workhouses of the county. The discussion was adjourned.

The Influenza Epidemic.

There is still no abatement in the number of persons attacked or in the virulence of the influenza visitation. From all parts of the north of Ireland the report is that the outbreak is more widespread and more severe than any since the first visitation.

(FROM OUR OWN CORRESPONDENT.)

The New Buildings of the Society of Surgery.

THE Society of Surgery has just entered into possession of its new buildings and for the future will occupy a mansion of its own where it will be absolutely in a position to receive and do honour to both members and guests. This is the fourth time that the society has changed its quarters. At its foundation in 1843 the society used to meet at the Hôtel de Ville where the Prefect of the Seine put a room at the disposition of the members. After the burning of the Hôtel de Ville the society held some meetings at the Practical School of the Faculty of Medicine, afterwards in the buildings of the Philomathic Society, and in 1852 in the buildings of the ancient Abbey of St. Germain des Prés, where also was held a school of dentistry. Here it remained until the present day, although somewhat straitened for room and under most inconvenient circumstances for the exhibition of cases. The new quarters are at 12, Rue de Seine, and are admirably fitted for their intended use. The room to be used for meetings is large and well lit, while artificial light is supplied by electricity. Behind the platform in the meeting room is a very large passage into which open two other rooms. One of these will serve as a committee-room and the other as a room for showing patients. On the first floor are three magnificent rooms which will serve for the library. The expenses of this new undertaking, which are very considerable, will be defrayed out of the funds which the society has in hand and a somewhat heavy personal contribution for which every member has made himself responsible. The medical press suggests that as the society has enlarged its place of meeting it should also become less select. The number of members is limited. Hospital surgeons themselves are not all members, but are only elected after a term of probation. As for surgeons who do not belong to the staff of a hospital—as, for instance, Doyen—no one, however celebrated, has ever been a member of the society. There is no definite rule to this effect, but at every election if a hospital surgeon presents himself he is nominated for election, for the society is entirely composed of his colleagues.

Crusade of the Medical Press against Travelling Spirit-bars.

The whole of the medical press is joining in a vigorous campaign initiated by the medical profession against alcoholism, and particularly against the refreshment carriages which some of the railway companies attach to their suburban trains, and which afford opportunity for workmen and employés to get drunk on the journey. The adoption of these carriages on the Government railways has called forth unanimous protestations. It is quite obvious that the chief way to lessen the consumption of alcohol is to lessen the opportunities open to idlers of getting it, and it might be hoped that the workman who is obliged to go home by train after his day's work would be able to escape in this way from the temptations offered by the public-houses which swarm in the vicinity of the factories. Once arrived at his home his surroundings begin to influence him all the more that he has no bad companions. Unfortunately the refreshment carriages do away with this beneficent interval, for firstly the drinks are much cheaper than in a public-house and the very carriage attracts the workman by being so much more comfortable than the ordinary carriage. The Northern Railway Company is doing its best to put down this new propaganda of alcohol and it is to be the more admired for this as its action deprives it of a certain amount of profit. The company has formally prohibited the use of these refreshment carriages on its system. There are, however, certain trains running successively over the lines of the Western Company and the Northern Company. On leaving the Western Company's terminus they pick up refreshment carriages belonging to the latter company, but when they arrive at Sannois, a station which belongs to the Northern Company, that company insists upon the carriage being uncoupled and the train is connected to it again on its return journey. As regards the other companies, however, it will be very difficult to make them give up an absolutely certain source of income solely with a view to forwarding social interests. It might be possible to lessen the evil by asking the Minister in charge of the railways to insist that the companies should make the price of places in their refreshment carriages very much higher.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Ladies as Members of the Berlin Medical Society.

A RATHER tumultuous meeting of the Berlin Medical Society took place on Jan. 10th, when a motion standing in the names of Dr. Zadek and Dr. Freudenberg concerning the admission of ladies into the society was discussed. According to Article 4 of the by-laws only a duly qualified medical man or a doctor *rite promotus* is eligible for membership of the Berlin Medical Society. Ladies engaged in medical practice here are therefore doubly ineligible—in the first place because they have all obtained their qualifications abroad and are therefore regarded by the German law as unqualified practitioners, and in the second place because in the by-law in question the term of "doctor promotus" (not promota) is used. Dr. Zadek and Dr. Freudenberg proposed that medical men and medical women should be eligible. The committee of the society interpreted the by-law as meaning that only a duly qualified medical person was eligible, thus excluding not only medical women, but also holders of the M.D. degree without the State qualification. Dr. Zadek urged that the Society ought to regard not the diploma, but the scientific attainments of the candidate, and that it was unjust to reject ladies because they were not entitled to become legally qualified in the present state of the German law. Professor Virchow in the name of the committee said that the Berlin Medical Society was not a body instituted for the purpose of determining whether a given individual was professionally competent or not; they had only to inquire whether a candidate possessed the State qualification or not. If they were to receive an unqualified person on the ground of his or her scientific attainments they would create by this action a kind of medical qualification granted not by the State, but by the society. After a long and animated discussion the motion of Dr. Zadek was rejected and the motion of the committee was accepted by a large majority. The attendance of members of the society at this meeting was far greater than on ordinary occasions, and the galleries of the society's room were crowded with spectators, among whom were several ladies.

Legislation with respect to Private Laboratories.

The *Vossische Zeitung*, a Berlin periodical, reports that a Bill relative to laboratory work will be introduced by the Government. It is said that the Bill will contain provisions by which investigators will be compelled to take precautions gainst the escape of pathogenic germs. The memorable outreak of plague in the hospital at Vienna, has induced the German Government to anticipate possibilities of this kind. The above journal rightly condemns legislation by which scientific research might be hindered, and is especially opposed to suppression of bacteriological work in private laboratories as suggested by influential parliamentary combinations. It draws attention to the fact that important researches, not only in bacteriology but also in other branches of medical science, have been carried on in private laboratories, for instance, the work of Professor Fritsch and Professor Hitzig on the localisation of function in the brain. Professor Koch himself whilst holding the obscure position of a medical officer of health in the province of Posen made his investigations on the nature of anthrax and other infectious diseases in his residence in the small country town of Wollstein. Nowadays there are well-equipped private laboratories in nearly every town of Germany and many medical men are prepared to examine sputa and other pathological material in their consulting-rooms. It would be very prejudicial to the profession if a new law prevented medical men from making bacteriological examinations elsewhere than in the State laboratories.

Precautions against the Plague.

A series of lectures and practical demonstrations on bubonic plague are being held in the Institution for Infectious Diseases. The duration of each course is 10 days and the Government has arranged that the heads of the State, provincial, municipal, and other public laboratories, and those assistants who have been engaged already at least one year in bacteriological work may attend the classes free of charge. The bacteriologists admitted to the classes at the expense of the Government are under an obligation to act as Government medical officers in the event of an outbreak of plague in this country. A number of non-official bacteriologists have also joined the classes at their own expense. Similar courses are held in the Imperial Health Office. In this way the Government hopes to have a staff of bacteriologists experienced in the recognition of plague.

Artificial Gout in Birds.

Dr. Kionka of the Pharmacological Institute of Breslau reports in the *Berliner Klinische Wochenschrift* that he has succeeded in producing gout in fowls by feeding them exclusively on meat. It has been made known by Ebstein, Kossa, and other authors that the administration of chromic acid, oxalic acid, and other toxic substances makes these birds gouty and Dr. Kionka tried to produce this pathological state by a special food. He therefore fed a series of fowls exclusively on horseflesh without fat and allowed them to drink as much water as they liked. The fowls were quite well at first, but after a few months symptoms appeared which were very like gout and which presented themselves in two different forms. In the first the birds walked very unsteadily and often fell down. On several occasions they were found lying on the ground with swollen joints and had no inclination for food. When a fit of this kind was over they seemed to feel better, their appetite returned, and the swelling of the joints decreased. In course of time the fits became more frequent, the feet of the birds were permanently swollen, they became unable to walk, could move about only by the help of their wings, and eventually died in a state of great emaciation. In the second form the fits were not so well marked, but characteristic tophi developed in the joints and between the tendons. Visceral gout was also observed with uric acid posits in the serous membranes and in the kidneys r. Kionka then investigated the metabolism of these birds nd found that the quantity of uric acid excreted was etween seven and 11 grammes per day. He thereupon dministered calcareous substances in the form of egg-shells, he result being that the excretion of uric acid increased about 40 or 50 per cent. The administration of this substance in gout has been recommended by Professor von Noorden and its favourable influence on the excretion of uric acid has now been ascertained.

Simultaneous Intra-uterine and Extra-uterine Pregnancy

A very rare case was lately shown to the Berlin Surgical Society by Dr. Hermes of the Moabit Hospital. A woman 30 years of age was admitted there in a serious condition, complaining of severe pain in the abdomen, which had come on during the previous 24 hours. The patient was very anæmic, her pulse was 120, and her abdomen panitic. On the left side of the abdomen a tumour felt and after some hours laparotomy was performed. The case proved to be one of extra-uterine pregnancy and a mole was removed. The patient recovered after the operation and was discharged from the about six weeks. It was observed that menstruation which had ceased three months before had not and that the uterus was still somewhat enlarged. When the patient returned after about a month the uterus had become still larger and it continued to grow during the following months. The symptoms pointed to the presence of a fœtus in the uterus and this diagnosis was verified six months later when the woman was delivered of a strong and normal child. In this case, therefore, extra-uterine and intra-uterine pregnancy occurred simultaneously, and it was very remarkable that the intra-uterine pregnancy came to a normal termination notwithstanding the operation which was performed on account of the extra-uterine pregnancy.

Large Ovarian Cyst.

At a meeting of the Zürich Medical Society Dr. Brunner, house surgeon to the Krankenasyl, Neumünster, showed one of the largest ovarian tumours that has yet been operated on. According to Dr. Brunner's investigations as to the size weight of tumours hitherto recorded, it stands fourth on list of large ovarian tumours. The tumour in question was an ovarian cyst weighing a total of 71 kilogrammes, or 155 English pounds, 60 kilogrammes, or 132 pounds, of which were fluid contained in the cyst. The tumour (to which the body of the emaciated patient seemed to be only an appendage) was first punctured and on slight fever ensuing was subsequently totally removed. The patient stood the operation well and without shock and recovered fairly well for four weeks, then slowly declined in health, death ensuing three months after the operation. The fatal issue proved to be due to a cancerous growth round the womb, evidence of which was not forthcoming at the time of the operation. In the discussion which followed the fact was mentioned that after laparotomy for large tumours latent carcinomatosis sometimes becomes evident, perhaps kept latent by the pressure of the tumour or stimulated to rapid growth by the removal of pressure.

Swiss Ambulance for South Africa.

At a meeting of the Red Cross Society at Aarau on Jan. 19th, it was decided to send an ambulance properly fitted out to the Transvaal. It will leave Genoa on Feb. 1st by the steamer *Kaiser*, and is due at Lorenzo Marques at the end of the month. It is to proceed to Pretoria. The English authorities have declined the offer of an ambulance. Dr Jean de Montmollin, Dr. René Koenig, and Dr. Fritz Sute have been elected as medical men. They have to serve for least six months and have to send medical reports to th President of the Red Cross Society. A sum of £700 has so far been collected by voluntary contributions to defray the expenses in connexion with the sending of the ambulance and further sums will no doubt be forthcoming. The choice fell on medical men who had had special surgical training in work as house surgeons.

ROME.

(From our own Correspondent.)

Influenza.

From day to day the "Ministero dell' Interno" (Hom Office) is receiving confirmation, all too authentic, of th ever-widening diffusion of influenza. Up to last night it w northern and central Italy that contributed the heaviest co tingents of cases, but now in Rome itself and farther sou the disease is numbering a progressively increasing prop tion of victims. This is due to the fact that the fo it at first assumed was very mild but that later it ma fested complications of a severer and less tractable ty Of the cities most gravely visited Leghorn heads the with no fewer than 15,000 cases and 700 in hospital. At Genoa the municipality has had to order the closing of all primary and secondary schools. Parma has 14,000 cases in the city alone and the hospital can admit no fresh ones. At Ferrara there are over 7000 cases, without including those of the suburbs or in the provinces, and there again the hospital has no room for more. At Pontedera (Tuscany) not a family has escaped and, as at Parma and Ferrara, the schools are closed from the illness of teachers and pupils alike. At Piacenza and Bologna the disease is becoming more extended as well as intensifying in character; at Turin it is taking a similar turn, and from 20 cases terminating fatally the proportion has risen to 40, and is still rising. All the public offices are "short of hands" from the illness of their *personnel*; not a house indeed is without one or more of its inmates in bed, and the schools are well-nigh empty though they are not yet officially closed Besides Pontedera other centres of population in Tuscany are severely visited—Ponsacco, near Pontedera, for instance, having 700 cases, and Prato numbering so many on the sick list that the scholastic institutions have had to send away teachers and students alike on leave of absence. At Florence the disease has effected a distinct foothold, though up to last night its character was mainly of the "benignant" form. Even in the absence of the generally fatal pulmonary complications, however, the "neurotic note" which it had "struck" at its outset is still present—chiefly in the prostration which attends the general malaise and which falls heaviest on the very old or the very infirm. All this aggravation in the diffusion and intensity of the malady is coincident with a longer continuance of wintry weather than Italy has experienced for well-nigh a generation—the snow on the uplands lying deeper than it has been known to do for thirty years and adding a deadlier chill to the prevailing tramontana.

La Villa Igiea, Palermo.

Such is the name given to the sanatorium recently opened near Palermo for the Cervello treatment of tuberculosis and designed as one of the chief attractions to the "Golden Shell" now asserting its claims as a winter-city and special health resort. THE LANCET of Jan. 13th, pp. 126–127, gave a brief account of the movement started in this sense by leading Palermitans, such as the Commendatore Florio and Baron Fassini, and it also referred to the deputation of British medical men who, as the guests of these gentlemen, had gone thither to inspect the sanatorium, its internal equipment and surrounding amenities, with a view to make their impressions known to the English-speaking world For four days the members of the deputation resided at Palermo, mostly at the sanatorium itself, familiarising themselves with the *modus operandi* of the Cervello treatment at the Guadagna Hospital and also at the sanatorium, informing themselves as to the inception of the latter and, more particularly, as to its appointments, its special therapeutics, and its advantages as to site and climate. The building, on one of the beautiful slopes of the suburban village of Acquasanta, was begun seven months ago and, thanks to the energy with which the 700 workmen were employed, it is now all but complete—rising in a noble park and approached by a fine carriage-drive, from which excursions of the most varied, picturesque, and exhilarating kind can be made in directions not a few. Internally the sanatorium, or I should say the Villa Igiea, is equal in accommodation to the largest hotels of continental capitals and its appointments might be called luxurious were they not so rigorously hygienic in every detail, assuring, among other advantages, an antisepsis of the most perfect description Every facility was afforded by the medical staff to their British colleagues for estimating the resources of the institution and forming a judgment as to the treatment therein pursued, and the attestation, volunteered by the deputation collectively and signed by its members individually, has, I understand, given much satisfaction to the Palermitan public, professional and lay: "We," the attestation runs, "after a three-days residence in the Villa Igiea have formed the opinion that the sanatorium is admirably well adapted for the cure of tuberculosis and other diseases of the lungs. It would be difficult to imagine as to climate and exposure a spot better calculated to attain this end, more especially in the practice of the 'open air cure,' now recognised universally as of fundamental importance in the treatment of tuberculosis."

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Decision in Kentucky with regard to "Osteopathy."

A DECISION has recently been rendered in a circuit court in Kentucky which appears to be the most far-reaching of any yet secured so far as the legal status of "osteopaths" in that State is concerned. An action was brought by a professor of the American School of Osteopathy at Kirksville, Missouri, against the State Board of Health of Kentucky to enjoin it from prosecuting him for practising his system in that State. By a section of the Kentucky statutes it is provided as follows: "Authority to practise medicine under this law shall be a certificate from the State Board of Health, and the said Board shall, upon application, issue a certificate to any reputable physician who is practising, or who desires to begin the practice of, medicine in this State who possesses any of the following qualifications: 1. A diploma from a reputable medical college legally chartered under the laws of this State. 2. A diploma from a reputable and legally chartered medical college of some other State or county, endorsed as such by the State Board of Health. 3 Satisfactory evidence from the person claiming the same that such person was reputably and honourably engaged in the practice of medicine in this State prior to Feb 23rd, 1864. 4. Satisfactory evidence from any person who was reputably and honourably engaged in the practice of medicine in this State prior to Feb 23rd, 1884, who has passed a satisfactory practical examination before said board." By another section of the statutes it is enacted that there shall be no discrimination against any institution, school, or system of medicine. The fact was admitted that the plaintiff held a diploma from the American School of Osteopathy at Kirksville, Missouri, and that the said school or college was legally chartered under the laws of that State. Therefore the question to be decided was whether the American School of Osteopathy at Kirksville, Missouri, could lay claim to the title of a "reputable" medical college. In order to determine this point fairly the Kentucky State Board of Health sent a committee of three of its most prominent physicians to investigate fully the Missouri College of Osteopathy. These medical men, after examining into its equipment, apparatus, and facilities for teaching; in fact, after making a full and complete and exhaustive investigation, unanimously came to the conclusion that the Kirksville School of Osteopathy was not a reputable medical college. In the cross examination of the witnesses for the prosecution, including several of the professors, the true nature of the said college was thoroughly revealed, and it was clearly shown that its claim to being a reputable school of medicine could not be upheld. Among the witnesses for the defence were many of the foremost physicians of Kentucky, one of these being Dr J Matthews of Louisville, president of the American Medical Association. Dr. Matthews testified that he understood the theory and practice of osteopathy and that osteopathy was not a system for curing diseases, but one which was to be feared for dangerous results which would naturally be caused thereby. He further remarked that the osteopathic treatment as a system was very foolish and would be more likely to kill patients receiving it than to benefit them. The committee as a whole handed in a report on the Kirksville College of which the following is an abstract: "We found a building and appointments adapted to the teaching of anatomy, physiology, normal histology, and chemistry. We found bones and diagrams, but no dissecting-room or physiological laboratory, and were informed that the students were not accorded the privilege of dissecting the human body with the necessary accruing benefits of such work. . . . The histological and chemical laboratories were well equipped with chemicals, microscopes, and other apparatus. All this relates to the study of the healthy man, there being no pathological laboratory, pathological specimens, bacterial cultures, charts, or diagrams available for teaching pathology and morbid anatomy. . . . Materia medica, which embraces the knowledge of drugs and medicines, and therapeutics, which is their application to the cure of disease, are repudiated by this school, its teaching claiming that in the treatment of disease the physician has no use for drugs and medicines, since the brain of ever his hand. ...... Without a dissecting-room, without he privileges of seeing and handling the muscles, vessels, erves, glands, and viscera of the body the committee cannot nderstand how the graduates of this school can have a practical knowledge of anatomy. ...... The Hon. Sterling B. Tovey, the judge of the court, after an eloquent summing up gave judgment for the defendants, the State Board of Health of Kentucky, declaring in the course of his speech that it is the policy of Kentucky to exclude charlatanry, and empiricism, and quackery from the State. There are unfortunately several States in America which not only legalise but encourage osteopathy, to the detriment alike of the general public and of the medical profession. It will be remembered that Kentucky has ever taken a firm stand against the practice of osteopathy within her boundaries, and reference has already been made in THE LANCET[1] to a decision of a Kentucky judge who, when a member of the osteopathic brotherhood charged with contravening the Kentucky Act in regard to the practice of medicine excused himself by asserting that he was merely manipulating with his hands, ruled that "any person who for compensation professes to apply any science which relates to the prevention, cure, or alleviation of the diseases of the human body, is practising medicine within the meaning of the statute." These decisions and the evidence of prominent medical men should open the eyes of the community at large to the uselessness of the treatment provided by professors of osteopathy.

Reforms in the Medical Department of the United States Army.

The American-Spanish war revealed many defects in the constitution of the medical department of the United States. In the first instance it was demonstrated that the number of army medical officers was inadequate to the needs of the regular army alone. The army at the outbreak of the war numbered 25,000 men and the medical corps consisted of 192 commissioned surgeons. The army was immensely increased by volunteers and the dearth of medical men had to be supplied by physicians taken from civil life. At the present time there are over 400 civilian surgeons doing duty with the American army. Until the Philippine campaign is brought to an end the Government will not decide as to the strength of the standing army of the United States, but there can be no doubt that it will be very considerably increased. This, however, is not the extent of the difficulty which faces the United States authorities. In order to meet any serious emergency which may arise the standing army will not alone be depended upon and the same policy will be pursued as was pursued in the war with Spain—that is, volunteer forces will be called out. The fact that an army surgeon requires special training to be able to fulfil his duties in an efficient anner is too palpable to need emphasis. Not only has he act as physician and surgeon, but at the same time the anitation and hygiene of camps falls within his phere of work. Thus a medical man taken from ivil life is suddenly thrust into a position for which he has had no training whatever except in so far as his knowledge of surgery is concerned. The evil results of following such a course were fully shown in the war with Spain. The Surgeon-General of the United States Army is about to present at the present session of Congress three Bills with a view of remedying the existing defective system. The first provides for an increase in the medical department of the army, the second secures regulations in regard to the efficiency of the department, and the third is for the raising of acting assistant surgeons to the rank of captain in the volunteer service. An increase in the medical department of the army is needed at once, for, as the *New York Medical Record* points out, "18 new posts have been established upon the sea-coast in the Department of the East and 10 have been established in the Department of the Columbia, including Alaska. There are now 11 independent garrisons in Porto Rico and a large number of independent commands in Cuba and the Philippines. These independent garrisons and commands require medical officers of experience and ability, and in addition all the higher executive offices of the medical department have to be filled with men of a rank commensurate with the positions which they occupy. It is absolutely impossible to do this with the present number of medical officers, hence the request of the surgeon-general for legislation as to an increase of the corps."

Cigarettes in the United States.

The analytical report of THE LANCET Sanitary Commission on American Cigarettes has aroused a considerable amount of interest in the United States. The "yellow" journals of the country have for a long time done their utmost to prejudice the minds of the general public against the cigarette. They have credited it with causing nearly every ill which human flesh is heir to. According to the accounts of some of the most sensational of these papers the cigarette is responsible for much insanity and is productive of crimes of all sorts and kinds from murder downwards. Of course many, or rather the majority, of these blood-curdling descriptions exist only in the imagination of the writers or are exaggerated and garbled out of all similitude of truth merely to pander to the love of the uncanny which has been cultivated in the minds of American readers of a certain class by the circulation of these vividly exciting journals. However, they have served their purpose and cigarette-smoking is regarded in the United States with the greatest distrust, and the cigarette itself is believed by the ordinary individual to be composed of the most pernicious, indeed poisonous, materials. The matter was taken up in New York some little time ago and various brands of cigarettes were tested analytically with the result that no injurious substances were found either in the tobacco or the paper. The finding of THE LANCET Analytical Sanitary Commission will doubtless go far towards rehabilitating the cigarette—that is to say, so far as its composition is concerned.

Obituary.

HENRY HANNOTTE VERNON, M.D., F.R.S. EDIN., M.R.C.S. ENG., L.M., J.P.,

MEDICAL OFFICER OF HEALTH OF SOUTHPORT.

DR. HENRY HANNOTTE VERNON, medical officer of health of Southport, died on Jan. 16th after a short illness, at his residence, Shipbrook, Cambridge-road, Southport. He had not been of robust health for a few months, but no anxiety as to his life was felt. He was nearly 68 years of age and was able to discharge his duties as medical officer of health up to a few days previously to the fatal termination, one of his last acts being to attend a committee meeting in that connexion.

Dr. Vernon was a well-known, popular, and enthusiastic medical officer of health, and was appointed to his post in Southport in 1873, devoting the whole of his time to the duties in 1888. He was born on March 25th, 1831, at Chatburn, near Clitheroe, and was the son of a Church of England clergyman—the Rev. William Vernon. After his school education he proceeded to Edinburgh to undergo his medical education, and in 1853 he took the M.D. degree. He always had the greatest affection for his *alma mater*. He became M.R.C.S. Eng. in 1854, and was a Fellow of the Statistical Society and of the Royal Society of Edinburgh and of the Incorporated Society of Medical Officers of Health. He had also been President of the Lancashire and Cheshire Branch of the British Medical Association and of the North-Western Branch of the Incorporated Society of Medical Officers of Health, and was a member of other learned societies. At the commencement of his career he practised in London and held appointments at St. Mary's Hospital, the Great Northern Hospital, and the Bloomsbury Dispensary. Later, however, he removed to Ashton-under-Lyne, where he had a successful career and became a member of the town council and a Justice of the Peace. In 1868 he went to reside in Southport, and after the passing of the Public Health Act of 1872 he was appointed medical officer of health, a position which he has worthily and successfully filled. During the whole of his official life he was on the best terms with the other officials, the members of the Health Committee, and of the corporation generally. He was a great advocate of the cause of education and was concerned in the establishment of the Southport Proprietary Schools, and as chairman of the

---

[1] THE LANCET, Sept 4th, 1897 (p. 607), and March [illegible] (p. [illegible]).

Birkdale School Board did much good and useful work, as he did also in connexion with the Southport Literary and Philosophical Society of which he was at one time president He was also a member of the Board of Management of the infirmary and was a late honorary medical officer of the Southport Convalescent Home To put it comprehensively, he was more or less connected with every movement which had for its object the development and improvement of Southport and was the trusted adviser in all sanitary matters to the corporation, and as was said of him by the mayor in moving a vote of condolence to his family, "He was a man of generous instincts and a man of very considerable literary ability He was a man whom they could esteem in private and in a public capacity, and a man whose friendship was extremely firm' Dr Vernon leaves a widow, two sons and two daughters to mourn their loss The two sons are members of the medical profession

ROBERT COLLUM M D GLASG, M R C P LOND, M R C S ENG

DR COLLUM, whose death at Surbiton on Jan 12th, in his 84th year, we have already recorded belonged to an Enniskillen family and received his medical education at Trinity College, Dublin where he was twice a gold medallist He was admitted a Member of the Royal College of Surgeons of England in 1836 He also studied at Glasgow University graduating there as M D in 1837 In the latter year he entered the Bombay Medical Staff Corps of the Honourable East India Company's service and was attached to Sir Charles Napier's staff throughout the conquest of Scinde He was the only medical man to accompany Sir Charles Napier upon his setting out for Scinde in the steamship *Zenobia* which left Bombay on Sept 3rd, 1842 with 200 soldiers Soon after getting to sea cholera broke out on board and in eight days 64 soldiers died in addition to sailors women and children Dr Collum served in the war was mentioned in despatches of the battle of Meanee, and acted as interpreter to the forces in Arabic, Hindustani, and Persian, Whilst in Scinde he had medical charge of all the troops as they returned from the first Afghan war and at the conclusion of the campaign he was appointed surgeon and superintendent to their Highnesses the ex Ameers of Scinde, and remained in that post for seven years He was also superintendent of the medical department at Aden, surgeon and superintendent of the Agency Jail at Hazareebaugh Bengal and assay master at the Bombay Mint In 1857 he retired from the service and upon his return to England he was elected President of the Society of Members of the Royal College of Surgeons, which position he occupied for seven years He also held the appointments of physician accoucheur to the Paddington Maternity and physician to the Western General Dispensary and was for 33 years medical officer to the Kingston-on Thames branch of the Metropolitan Convalescent Institution He became a Member of the Royal College of Physicians of London in 1859

CHARLES POPE WALKER M B DURH, M R C S ENG,

MAJOR R A M C

THE death is announced from dysentery at Ladysmith on Jan 5th of Major Charles Pope Walker, R A M C He was the youngest son of the late J N Walker of Bedford and was born in 1859 He obtained his medical education at Guy's Hospital whence he qualified, becoming M R C S Eng in 1883 and L S A in 1885 and at Durham, where he graduated as M B In 1886 he entered the medical service of the army as a captain in the Royal Army Medical Corps In 1887 he went to India and was attached to an English regiment serving at Quetta and afterwards in the North West and Central Provinces In 1892 he returned to England and was then attached to the Guards in Ireland In 1895 he served in the Mauritius where he remained until 1898 when he went to the Cape and afterwards to Natal In November, 1899 he proceeded with the troops to the front and had charge of the hospital at Dundee and was present at the battle of Elandslaagte afterwards retiring with the forces from Dundee to Ladysmith where he rendered valuable medical services He obtained the rank of Major in July of last year and married in 1895 the third daughter of the late Colonel W Famplin of Brighton He was a keen and most fearless sportsman with big game and during his Indian career he was noted for the number of tigers and bears which fell to his rifle

Medical News.

SOCIETY OF APOTHECARIES OF LONDON—In January the following candidates passed in the subjects indicated —

Surgery—T P Allen (Sections I and II), Manchester J R Bentley (Sections I and II), Middlesex Hospital C H Brookes (Sections I and II), Durham and St. George's Hospital A. McC Dallas (Section II) Guy's Hospital; J M Edwards (Section II) *Charing-cross Hospital* W St G G Hill, St Mary's Hospital D T C Jones (Section I) University College Hospital E C Scarlett (Section II) Royal Free Hospital H L Weston (Section II) St George's Hospital and T R Wilshaw (Section I) Birmingham

Medicine—F G Aldrich (*Section II*) *Charing cross Hospital* A. St. J Bateman (Section I) King's College Hospital C H Brookes (Sections I and II) Durham and St George's Hospital; I Cator St. Bartholomew's Hospital D T C Jones (Sections I and II), University College Hospital, and E. C Scarlett (Section *II*) *Royal Free Hospital*

Forensic Medicine—C H Brookes, Durham and St George's Hospital A McC Dallas, Guy's Hospital D T C Jones University College Hospital and L. G W Tyndall St. Mary's Hospital

Midwifery—A. H Bell Cork and Guy's Hospital; P C Burgess Middlesex *Hospital* A A P *Clarke St Thomas's Hospital* J S Goodall Middlesex Hospital K Grube Bonn D T C Jones, University College Hospital E R Risien St Bartholomew's Hospital J Waters Middlesex Hospital and H Whittaker, Cambridge.

The diploma of the *Society* was granted to the following candidates, entitling them to practise Medicine Surgery and Midwifery:—Messrs J R Bentley I Cator J M Edwards, K Grube W St. G G Hill E C Scarlett H E Weston and H Whittaker

UNIVERSITY OF CAMBRIDGE—At the Congregation held on Jan 18th the following graduates in arts were admitted to the degree of Bachelor of Surgery —

Edwards Williams Hedley, King's Alexander Thomas Fraser and Richard Ernest Sedgwick Gonville and Caius Redcliffe Nathan Salaman Trinity Hall and John Everard Linnell Selwyn Public Hostel.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND—At a stated meeting of the President and Fellows of the Royal College of Physicians of Ireland held on Jan 12th, the following gentlemen were admitted as Members E J McWeeney M D R U I, and W A Winter, M D Dub —At a special meeting of the President and Fellows of the Royal College of Physicians of Ireland held recently the President (Dr J W Moore) was nominated to represent the College upon the Committee of Inquiry into the Health of Dublin which his Excellency the Lord Lieutenant suggested should be appointed by the Local Government Board The following resolutions were adopted —

That the President and Fellows of the College reiterate the deliberate opinion expressed in the conjoint report of the Royal College of Physicians and the Council of the Royal College of Surgeons (Ireland) on the death rate of Dublin 1881.

That the city of Dublin is and has been *unhealthy in an excessive* degree and its extraordinary death rate is attributable not to errors of computation or irremediable circumstances, but to long continued disregard of sanitation and the omission to enforce the legal means provided for a remedy

The President and Fellows are further of opinion that the excessive mortality within the city demands from the civic sanitary authority the most firm energetic and persevering execution of the powers entrusted to it to secure even a partial amelioration of the existing evils; and the health of the city will be likely to deteriorate still further unless dealt with by a new and radical method much more vigorous than that which has hitherto been adopted

LITERARY INTELLIGENCE—Mr H K LEWIS announces that he is about to publish a work by Dr S A Knopf of New York on "Pulmonary Tuberculosis its Modern Prophylaxis and the *Treatment* in Special Institutions and at Home This work contains descriptions and illustrations of the most important Sanatoria of Europe the United States and Canada Also "Letter, Word and Mind *Blindness* by Dr James Hinshelwood, a second edition of Dr G E Shuttleworth's book on "Mentally Deficient Children, their Treatment and Training much enlarged and revised and a translation of Professor Edinger's "Anatomy of the Central Nervous System of Man and of Vertebrates in General opinion the appearance of staleness was kept away by the preservative. During the period from May to December they examined about 200 samples of butter expressly for boric acid and borate and found 56 with it in proportions ranging from two to 62 grains per pound. Recently they examined about 20 samples of jam and found 15 of them preserved with salicylic acid, the quantity varying from a quarter of a grain in strawberry to four and a half grains in black-currant per pound of jam. The amount of salicylic acid in some temperance drinks usually consumed by children was perfectly astounding. In lime-juice cordial they had found from 20 to 103 grains per gallon, in lemon squash 50 grains per gallon, in ginger wine from 49 to 115 grains per gallon, in raspberry wine from 87 to 133 grains per gallon, in orange wine from 94 to 106 grains per gallon, and in black-currant wine from 47 to 140 grains per gallon. He had performed some artificial experiments with regard to digestion and found that salicylic acid had a very prejudicial effect in certain cases. As to colouring, his experience went to show that peas were almost invariably coloured by compounds of copper—a practice which he thought required very strict control. He had seen peas coloured by so small a proportion as a quarter of a grain of sulphate of copper per pound, and if this sufficed, as it apparently did, he did not see why a larger quantity should be used.

Dr. **JAMES ROBERT KAYE**, Wakefield, medical officer of health of the West Riding of Yorkshire, was the next witness and in answer to the **CHAIRMAN** said that the area for which he was responsible had a population, roughly speaking, of 1,250,000. When this Committee asked for information he set on foot an inquiry into the question of milk and butter with which some progress had been made, though it was not yet completed. This inquiry showed that the use of preservatives was greatly on the increase and especially so during the last two or three years. They had found milk-dealers, dairymen, farmers, butchers, and even tripe-dressers using them. Among 17 samples of milk taken in hot weather they found 13 with boric acid or formalin, while 13 samples taken in similar conditions, but during the months of October and November, were entirely free from either preservative. These samples were taken from vendors in the streets or from milk-shops. The majority of the people to whom he spoke on the subject said the preservatives were necessary, though he could not say they had convinced him of this; indeed, his opinion was that preservatives in dairy produce were not necessary, and he certainly considered them undesirable. He was afraid the provisions of the dairy and milkshops regulations were not very stringently enforced and their evasion was rather facilitated than otherwise by the use of preservatives. When a man employed them he thought, for instance, that cold instead of boiling water sufficed to clean his vessels. Indeed, he found that people in the dairy trade had wonderful ideas about preservatives apart altogether from their preserving effect—ideas about their counteracting insanitary conditions in cowsheds, about the excessive use of brewery grains, about their effect upon milk taken from cows with diseased udders, and the like. He had prepared a series of tables for the consideration of the Committee. The first of these gave a few examples of advertised preservatives. One of them was advertised as "medically guaranteed, absolutely harmless, and pure" and as "extensively employed in the hotel, household, restaurant, and ship's cabin." This preservative contained 85·5 per cent. of boric acid and 14·5 per cent. of borax, and the directions for use were for milk seven grains per pint, for butter 31 grains per pound, and for sausage 30 grains per pound. Another of these preservatives was advertised as "harmless and effective, safe and reliable, none need be afraid to use it." It also contained 85·5 per cent. of boric acid and 14·5 per cent. of borax, and the directions for use were for sausage, &c., 44 grains per pound and for gravy, soups, &c., nine grains per pint. A third preservative, which contained 100 per cent. of boric acid, was advertised as "harmless and effectual," and the directions for its use were for milk seven grains per pint, but "for small consumers a teaspoonful will be sufficient for a quart of milk," for cream nine grains per pint, and for sausage 45 grains per pound. Another preservative which had not been analysed was said to be "totally harmless to the most delicate child" and the directions for its use were for milk 11 grains per pint and for butter 125 grains per pound. His experience went to show that preservatives were more frequently present in adulterated than in pure articles. He had attempted to show that this increasing and indiscriminate use of preservatives was not without effect upon public health. He had prepared a table showing the infantile mortality in England and Wales during the 20 years 1878–1897 arranged in five-yearly periods. For comparison the general death-rate of the same period was also shown:—

Five-yearly period. (1)	Number of deaths of infants under one year per 1000 births. (2)	(3)	General death-rate per 1000 living (all ages). (4)
1878–82	142	Corresponding to the following increased loss of infant life in actual numbers.	20·3
1883–87	143	4,481	19·4
1888–92	146	17,788	19·0
1893–97	152	45,641	17·8

It would be seen that instead of an improvement which one might expect from modern improved sanitary conditions there had been an increase in the sacrifice of infantile life and that this increase was coincident with a steady decrease in the general death-rate. The question, therefore, arose, What were the factors which produced this infantile mortality? Medical men might say something about the employment of mothers in factories and other places, but this employment went on all the year round, while the increase in the infantile mortality was practically limited to the third quarter of the year. This quarter was the quarter in which the maximum amount of milk was used amongst children, and he had endeavoured to show that the use of preservatives in milk might at any rate play a part in bringing about the mischief. In another table he displayed the rates of infantile mortality during one eight-year period (1891–98) in England and Wales and various parts of the country—also the quarterly distribution of the same:—

—	Number of infant deaths (under one year) per 1000 births. Eight years 1891–98.	Quarterly distribution of such infant deaths. Average of eight first quarters.	Average of eight second quarters.	Average of eight third quarters.	Average of eight fourth quarters.
England and Wales	152	147	129	183	150
33 large towns ...	171	152	141	229	163
Five county boroughs in West Riding of Yorkshire ...	176	154	147	239	165
West Riding Administrative County	154	145	139	171	161

It would be found that not only was practically the whole of the increase in the third quarter of the year, but that during the last eight years there had been an improvement in the first and second quarters, while the fourth quarter had been stationary. Considering the great sanitary progress and the improvement in the general death-rate this increase in the infantile mortality in the third quarter of the year must be due to something unusual, and the question became, What was it that was unusual? As far as he could see the use of preservatives was unusual and was increasing every day and therefore he was inclined to put down some at any rate of this increase in infantile mortality to excessive use during the third quarter of the year of preservatives in milk.

By Dr. **BULSTRODE**: He did not attempt to establish that autumnal diarrhœa was due to the use of preservatives in milk, but that it might be a factor in preventing a fall in the mortality from infantile diarrhœa. Preservatives prevented the milk from becoming manifestly sour, but while that was so they might not prevent other action going on in the milk which was deleterious to the infant consuming the milk. His experience was that in hot weather over 70 per cent. of the samples had preservatives, while in winter they found that practically none had them. He intended to carry his investigations further and hoped to get more information which would enable him to decide whether preservatives were only used in milk in hot weather. His view was that in the present state of things infants and invalids suffered and that if the use of preservatives went on unchecked healthy adults would also suffer.

By Dr. **TUNNICLIFFE**: In his district tinned milks were largely used in some places, but not by the class of people among whom the infantile mortality was greatest.

Mr. **OTTO HEHNER** (public analyst for several districts of England) next gave evidence. He had devoted special attention, he said, to butter and had found that at least 90 per cent. of the samples he had examined contained borax preservatives. Nearly all the butter in the rural districts of the south of England was coloured, but in the Midlands he had sometimes found uncoloured butter. A few years ago annatto was the colour used, but now the practice was to use aniline dyes, though not in quantities to be injurious to health. He frequently found colouring matter in milk, and while he did not like the practice he did not regard it as a very urgent matter.

The Committee then adjourned.

MONDAY, JAN. 22ND.

The Committee held another meeting to-day, when Sir **HERBERT MAXWELL** again presided.

Mr. **H. DROOP RICHMOND**, resident analyst to the Aylesbury Dairy Company, London, was the first witness examined, and in answer to Professor **THORPE** he said that although the Aylesbury Dairy Company did not employ preservatives in milk or cream or in any butter made by them he had given considerable attention to the subject and he had prepared for the Committee a table showing the results of analyses with reference to boric acid and salicylic acid. In his experience he found that the preservatives most favoured were a mixture of borax and boric acid and formalin. When the latter was added to milk it appeared to toughen the proteids, probably the casein chiefly. That was shown by the fact that when the fat was heated with hydrochloric acid the casein took very much longer to be dissolved upon boiling than if no formalin had been added. He should say that first of all a combination had taken place and there was some ground for assuming that the casein was in a more insoluble form and probably a form more difficult of digestion. He should not like, however, to say that this conclusion was entirely justified. In cream there was sometimes used a solution of lime and cane sugar which acted as a preservative, retarding the time when the evidence of curdling and souring was shown to the consumer. This solution also made the cream look thicker. At one time the Aylesbury Dairy Company added 0·2 per cent. of boric acid to cream, but they no longer did so. They found that the presence of the preservative was objected to by a considerable section of the public, and after experimenting they discovered that they could supply cream in a fresh state without it. At one time they used boric acid for butter. There were two ways which they had of using it; one was to wash the butter with a solution directly after churning it, and the other was to mix the acid with the butter and work it in. Now, however, they no longer used preservatives in the butter which they made. The butters from France which they imported were habitually preserved, and having regard to the methods of production and collection in that country he was afraid that unless some preservative were added there might be trouble in regard to keeping. He did not think, however, that the use of boric acid compounds was absolutely necessary, even in these butters, for a small percentage of salt could be added with equally good results. Up to last year he found that Australian butters were invariably preserved, but last year he met one or two samples which were free from preservatives. These samples when they reached the laboratory were in as good condition as the others, and therefore he should infer that there was no need for preservatives in Australian butters. Boric acid and salicylic acid were preservatives which could be estimated with ease and accuracy, but in the case of formaldehyde it could not at the present moment be estimated quantitatively.

By Dr BULSTRODE: His opinion was that if milk would keep sweet for 18 hours that was sufficient for their trade, and he should consider that a fair limit for all classes of trade. He did not see why milk should be kept longer than 18 hours. At a temperature of 70° F. milk would keep for 34 hours before it turned sour, at a temperature of 80° for 22 hours, and at a temperature of 90° for 15 hours. In the hottest weather of last year the maximum temperature of milk as it arrived at their dairy at Bayswater was 77° F. and of milk after it had gone on a round and been brought back to the dairy 83° F. He thought that he should be right in assuming that the average temperature would not have been higher than 80° F. In these circumstances they found that they could supply fresh milk and allow customers three or four hours at least for its consumption.

By the CHAIRMAN: Instead of limiting the amount of preservative used he should rather advocate prohibition. The preservatives came into the hands of dairymen under fancy names and unless they had special information they did not know the quantity of the preservative they were using or its nature and not only so but the same article might be dosed several times by different people. The only colouring matter used by the company was annatto.

Mr HATTERSLEY, managing director of the Aylesbury Dairy Company, said, in reply to the CHAIRMAN, that the greater part of their milk supply came from Berkshire and Wiltshire, though some came from a county so remote from London as Cheshire. All the milk came free from preservatives. The opinion of the company was that preservatives were not necessary. During 1899 they had well over 5,000,000 deliveries of milk and only 78 letters of complaint about sourness, which showed, he thought, that the milk gave satisfaction to their customers. He considered that they were fairly well served by the railway companies. Occasionally it happened that the milk was sent to London in a fish truck or in a waggon or van which had contained fish and in consequence the flavour of the milk was affected. In the contracts they made with the farmers they had strict provisions as to cooling the milk, for milk could not be brought to London from a distance in proper condition unless it had been carefully cooled. The demand for pasteurised milk was small in London, though there was a considerable trade in sterilised milk. The company separated the cream at their dairy at Bayswater with the exception of one small lot which they obtained from a farm close to London and they used no preservatives for the cream. In 1899 they had six letters of complaint about cream, which averaged about 0·05 per 1000 quarts of cream delivered. All the butter they made themselves was free from preservatives. With regard to the colouring of milk they had tried several times to do without it but customers objected and they had had to resume colouring. He regretted this much because he should greatly prefer to have the milk sold uncoloured.

By Dr BULSTRODE: The company had kept butter in their own dairies for a fortnight without ice and he had no doubt if the methods of the French butter making industry were altered the French butter could be imported into this country free from preservatives.

By Professor THORPE: Their milk supply in a year amounted to 1,500,000 gallons and it came from about 50 farms whose average distance from London was from 70 to 80 miles. This supply was distributed among considerably over 100,000 persons.

Dr DUPRÉ of the Home Office was next examined and in answer to the CHAIRMAN he said he objected to preservatives in milk because in his opinion they did away with the guarantee of cleanliness. He took this objection quite apart from the question of harmfulness about which no doubt there was great difference of opinion. Further, he thought it objectionable that a chemical substance should be mixed indiscriminately with food unknown to the consumer. Few people visited and inspected dairies, but every person knew when milk was sour and this constituted a great protection. He objected to preservatives because they took away this protection. Having regard to the fact that milk was the only food of infants and invalids it was most important that it should be really good and therefore he was more concerned about it than about the other articles in which they found preservatives.

The CHAIRMAN: Are you aware that preservatives are largely used in fish?

Dr DUPRÉ: Yes from hearsay. I have never got fish to analyse.

The CHAIRMAN: Would you think it important that it should be known?

Dr DUPRÉ: Yes. I would have the same objection in the case of fish as I have in the case of milk. Fresh fish is a guarantee that it has been recently caught.

The CHAIRMAN: Are you aware that [illegible] taken in the North Sea are [illegible] kept for many days and even weeks before being brought to the market?

Dr DUPRÉ: I did not know that.

The CHAIRMAN: If that were proved to be the case would you think it a [illegible] thing?

Dr DUPRÉ: I should think it in the highest degree undesirable.

The CHAIRMAN: Have you never experienced a bad sole?

Dr DUPRÉ: Yes, but I never attributed it to any keeping of that kind.

Further [illegible] by the CHAIRMAN Dr DUPRÉ said that in his [illegible] colouring matter which was considered [illegible] [illegible] any [illegible]. He should certainly not allow copper to be [illegible] peas, for while one person might take with impunity a certain quantity of copper a much less quantity might cause serious mischief to another person. He should prohibit the use of copper in peas simply because one never knew how it might affect people. A mere declaration that the peas were artificially coloured would not, in his opinion, meet the case nor would a declaration that they were coloured with copper, because the consumer might not be aware that copper was poisonous. If the declaration were to the effect that the peas were coloured with a poisonous matter then it might have some effect.

By Dr TUNNICLIFFE: He considered it to be the duty of people who employed colouring matters to prove that they were not injurious and if they failed to do so to give up the practice.

Mr JOHN MITCHELL HARRIS, managing director of C. and T. Harris and Company, bacon curers, Calne, Wiltshire, and deputy chairman of the Bacon Curers' Association, gave evidence as to the use of borax in the bacon industry. He stated that his own firm employed nothing beyond salt and saltpetre and found no need for borax, even in connexion with their export trade.

The Committee adjourned, to meet again at the end of a fortnight.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BAILEY, BERNARD, F. G., M.R.C.S., L.R.C.P., has been appointed Second House Physician for the City of London Hospital for Diseases of the Chest, Victoria Park, E.

BLAIR, A. B., M.B., C.M. Edin., has been appointed Medical Officer for the Banwell (first) Sanitary District of the Axbridge Union, vice D. Lawson, resigned.

DECK, F. J., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 2 Sanitary District by the Hastings Board of Guardians.

FORREST, J. S., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer and Public Vaccinator by the Alnwick Rural District Council.

FRASER, S., M.B., C.M. Edin., has been appointed Medical Officer for the Edmonton Sanitary District of the Edmonton Union, vice J. Hodges.

HEATON, GEORGE, M.D., B.Ch. Oxon., F.R.C.S. Eng., L.R.C.P. Lond., of 3, Temple-row, Birmingham, has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, and to act for County Court Circuit No. 21.

HEDLEY, W. F., M.B. Edin., L.R.C.P., L.R.C.S., L.F.P.S. Glasg., has been appointed Medical Officer for the Hallaton Sanitary District of the Uppingham Union, vice H. A. Cruttwell, resigned.

HIGGINS, ALEXANDER G., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the West Kent General Hospital, Maidstone, vice F. T. Travers, resigned.

HOPE, A. A., M.B., B.S. Durh., has been appointed Medical Officer for the Fifth Sanitary District of the Daventry Union, vice F. W. Fowke, resigned.

JONES, CHARLES SILLIFANT, M.R.C.S. Eng., L.S.A., has been re-appointed Medical Officer of Health for Chichester.

LAMONT, J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer to the Poplar Workhouse, London.

LIVERSIDGE, WM., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed a Civil Medical Officer and has proceeded to the seat of war, South Africa.

LOW, R. B., M.D. Edin., D.P.H. Camb., has been appointed an Assistant Medical Officer to the Local Government Board.

MCCALL, ANTHONY, M.D. Glasg., has been appointed Surgeon to the Throat and Ear Department of the [illegible] Hospital, Bournemouth.

MACKIE, G., M.B., C.M. Aberd., has been appointed Assistant Medical Officer for the Infirmary and Workhouse of the Parish of St. George in the East, London, vice [illegible] K. [illegible], resigned.

MANBY, L. P., M.D. Camb., M.R.C.S., D.P.H., has been appointed an Officer on the staff of Medical Inspectors of the Local Government Board.

NEVINS, J. F., M.B. Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse, Liverpool.

PARSONS, H. F., M.D. Lond., M.R.C.S., D.P.H. Cambridge, has been appointed Assistant Medical Officer and Medical Inspector for General Sanitary Purposes to the Local Government Board.

PERCIVAL, A. S., M.B. Camb., has been appointed Honorary Surgeon to the Newcastle Eye Infirmary.

POWER, W. H., M.R.C.S., has been appointed Medical Officer to the Local Government Board, vice the late Sir R. Thorne.

PRATT, W. H., M.R.C.S., has been re-appointed Medical Officer of Health by the Wetherby and [illegible] Rural District Council.

Rhys, Watkin Llewellyn, L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed Medical Officer and Public Vaccinator for the Aberdare District by the Merthyr Tydvil Board of Guardians, vice D. Davies, resigned.

Ridley, Walter, M.B., M.S. Dunelm, F.R.C.S. Eng., has been appointed Surgeon to the Royal Infirmary, Newcastle-on-Tyne, vice *Professor Page, retired.*

Smallwood, Savage, M.A., M.B. Oxon., F.R.C.S., has been appointed Surgeon to the Wolverhampton Hospital for Women.

Stamper, J. T., Civil Surgeon, has been appointed to do duty in connexion with the medical charge of Pembroke Dock.

Sutton, C. R. A., M.D. Camb., has been appointed Medical Officer for the *Seventh Sanitary District* of the Bromley Union, vice F. Shapley.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

Bath General or Royal Mineral Water Hospital, Bath.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and apartments.

Birmingham and Midland Eye Hospital, Birmingham.—Assistant House Surgeon. Salary £60 per annum, with apartments and board.

Bolton Infirmary and Dispensary.—Junior House Surgeon for twelve months. Salary £80 per annum, with apartments, board, *and attendance.*

Bootle Borough Hospital, Liverpool.—First and Second House Surgeons. Salaries, senior £80, senior £50 per annum, with board, lodging, and washing. Apply to the Chairman, Hospital, Derby-road, Bootle.

Borough of Southport.—Medical Officer of Health for the Borough. Salary £500 per annum. Apply to the Town Clerk, Town Hall, *Southport.*

Bristol Royal Infirmary.—Resident Officer. Salary £40 per *annum,* with board, lodging, and washing.

Brixton Dispensary, Water-lane, Brixton.—Resident Medical Officer *for two years,* unmarried. Salary £150, with furnished apartments, attendance, coals, and gas.

Cardiff Infirmary.—Assistant House Surgeon and Assistant House Physician for six months each. Salaries at the rate of £50 per annum, with board, washing, and apartments.

Central London Ophthalmic *Hospital, Gray's Inn-road,* W.C.—House Surgeon. Salary at the rate of £50 per annum, with board and residence in the hospital.

City of Liverpool.—Assistant to the Medical Officer of Health. Salary £350 per annum, subject to certain conditions. Applications to the *Town Clerk, Town Clerk's Office,* Liverpool.

East Suffolk and Ipswich Hospital, Thorofare, Ipswich.—Second House Surgeon for one year, unmarried. Salary £60 per annum, with board, *lodging, and washing.*

Eastern Dispensary, Leman-street, Whitechapel, London.—Physician. Honorarium £50 a year.—Apply to the Secretary, 60, *Great Prescot*-street, London.

Evelina Hospital for Sick Children, Southwark, London.—Surgeon to Out-patients.

Eye and Ear Hospital, Tunbridge Wells.—House Surgeon for one year. Salary £60, with board and residence.

General Infirmary, Leeds.—Resident Ophthalmic *Officer. Salary* £50 a year, with board and lodging.

Gravesend Hospital.—House Surgeon. Salary £80 per annum, with board and residence.

Grove Hall Asylum, Bow, London.—Junior Assistant Medical Officer. Salary at the rate of £120 per annum, with board, apartments, washing, and attendance.

Hospital for Diseases of the Throat, Golden square, London.—Registrar and Pathologist. Honorarium of 25 guineas per annum.

Hospital for Women, Soho-square (the London School of Gynæcology).—Clinical Assistantships.

Hulme Dispensary, Dale-street, Stretford-road, Manchester.—House Surgeon. Salary £130 per annum, with apartments, attendance, coal, and gas.

Leicester Infirmary.—House Physician for twelve months. Salary £100 per annum, with board, apartments, and washing.

Loughborough and District General Hospital and Dispensary, *Loughborough.—Resident House* Surgeon. Salary £100 per annum, with furnished rooms, attendance, and board.

Mason University College, Birmingham.—Lecturer on Osteology and Chief Demonstrator of Anatomy.

Metropolitan Asylums Board.—Assistant Medical Officer (Junior) at the Asylum at Caterham, in Surrey, *unmarried.* Salary £120 per annum rising to £150, with board, lodging, attendance, and washing (subject to statutory deduction). *Apply to the Clerk to* the Board, Norfolk-street, Strand, London.

Miller Hospital and Royal Kent Dispensary, Greenwich-road.—*Junior Resident Medical Officer for six months. Salary* at the rate of £40 per annum, with board, attendance, and washing.

Nottingham City Asylum.—Second Assistant Medical Officer, unmarried. Salary £125, *with board, apartments, and washing.*

Nottingham General Dispensary.—Assistant Resident Surgeon, unmarried. Salary £140 per annum, all found except board.

Royal Cornwall Infirmary, Truro.—House Surgeon, unmarried. *Salary £85, with board* (excluding stimulants) and apartments.

Royal Hospital for Sick Children, Glasgow.—Honorary Oculist at the Dispensary.

Royal Infirmary, Sheffield.—House Surgeon for three years. Salary £120 per annum, with board, lodging, and washing.

Royal South Hants Infirmary, Southampton.—Assistant House Surgeon for six months. Salary at the rate of £50 per annum, with rooms, board, and washing.

Salisbury Infirmary.—House Surgeon, unmarried. *Salary £100* per annum, with board, lodging, and washing.

St. Mark's Hospital for Fistula and other Diseases of the *Rectum, City-road, London.*—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

Stockport Infirmary.—Junior Assistant House Surgeon for six months. Salary at the rate of £2 per mensem, with residence, board, and washing.

University College, London.—Assistant *Surgeon* and Assistant Physician.

West Kent General Hospital, Maidstone.—Assistant House Surgeon *for six months.* Honorarium at the rate of £50 per annum, with board and residence.

Births, Marriages, and Deaths.

BIRTHS.

Aplin.—On Jan. 22nd, at Hill House, Sneinton, Nottingham, the wife of Dr. Aplin, medical superintendent, *Notts. County Asylum, of* a daughter (Alys Arundel).

Boddie.—On Jan. 23rd, at Bruntsfield place, Edinburgh, the wife of *George P. Boddie, M.B.,* of a son.

Brodie.—On Jan. 16th, at Fernhill, Wootton-bridge, Isle of Wight, the wife of C. Gordon Brodie, F.R.C.S., of a daughter.

Busteed.—On Jan. 21st, at Ellesmere, *Shropshire, the wife of John* Hancock Busteed, L.R.C.P., L.R.C.S., L.S.A., of a daughter.

Fison.—On Jan. 20th, at The Cedars, Manor-road, Salisbury, the wife *of Edmund Towers Fison,* M.D., of a son.

MacLeod.—On Jan. 24th, at *Harley-street,* W., the wife of J. *M. H.* MacLeod, M.D., of a son.

MARRIAGES.

Blair—Sheriff-Macgregor.—At 32, Athole-gardens, Glasgow, on Jan. 16th, by the Rev. David Strong, D.D., Hillhead, and *Rev.* William Wilson, M.A., Trossachs, Andrew Buchanan Blair, M.B., C.M., Banwell, Somerset, to Constance Elizabeth, daughter of the late *George Sheriff-Macgregor,* Esq., Glengyle, Perthshire.

Bridgeford—Cumberland.—On Dec. 13th, 1899, at St. George's Church, Queen's Cliff, Victoria, by the *Rev. H. Wilkinson,* Walter Bridgeford, M.R.C.S. Eng., and L.R.C.P. Ed., of Boulder, West Australia, to Florence Landale, daughter of the late Captain R. F. W. Cumberland, H.M.'s. 96th (Manchester) Regiment.

Meakin—Ball.—On Jan. 6th, at St. Giles's Church, Cambridge, by the Rev. F. Buxton, vicar, *assisted* by the Rev. Arthur Cooke, M.A., of King's College, Harold Budgett Meakin, M.D. Lond., of the Indian Medical Service, son of the *late Edward Meakin of* Hampstead, to Frances Amelia, elder daughter of Sir Robert Ball, Lowndean Professor of the University of Cambridge.

Walker—Green.—*On Jan. 18th,* at St. John the Baptist's, Paignton, Cyril Hutchinson Walker, M.B., younger son of the Rev. John Walker, *rector of Bradwell, Suffolk,* to T. Caroline, eldest daughter of the late Rev. J. H. B. Green, rector of Normanton, Ashby-de-la-Zouch.

DEATHS.

Adney.—On Jan. 17th, at Whittlesey, Cambs., Alfred Adney, M.R.C.S., aged 76.

Bond.—On Jan. 13th, 1900, at Greenwich Infirmary, Harry Bond, M.R.C.S., L.R.C.P. (St. Bartholomew's Hospital), of pneumonia after a short illness, aged 26 years.

Burger.—On Jan. 21st, at Finsbury-square, Alexander Burger, M.D., suddenly, aged 61.

Dunbar.—On Jan. 19th, Robert Pearson Dunbar, M.D., Park House, *Blackburn.*

Easby.—On Jan. 23rd, William Easby, M.D., L.R.C.P., L.M., L.R.C.S., of 6, Chatsworth-road, Brondesbury, N.W., late of Peterborough, aged 55 years.

Vernon.—On Jan. 16th, at *Shipbrook,* Cambridge-road, Southport, Henry Hannotte Vernon, M.D., F.R.S.E., aged 68 years. For *27 years medical officer of health* for Southport.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

QUACKS AND THE WORKMEN'S COMPENSATION ACT.

AT the Forth County Court last week a collier claimed under the Workmen's Compensation Act half of his wages for the 14 weeks of enforced idleness due to a slight accident which had happened to him in the colliery workings, from the roof of which a stone had fallen on to his hand. He was attended by the works surgeon, Mr. Ivor Lewis, who found at the end of about 10 days that there was a collection of pus on the arm which it was necessary to let out, but the collier was very much averse to this treatment and preferred rather to place himself under the care of a certain old woman in the village who was reputed to be in possession of a "salve" which would speedily effect a cure. The result of this decision was not quite so serious as it might have been, but it was three months before the hand returned to its normal condition. In assessing the amount of compensation to which the claimant was entitled the judge very properly took into consideration the fact that the man wilfully prolonged his absence from work, and awarded him only eight weeks' half-pay instead of the 14 weeks claimed. This decision should serve to impress other workmen similarly circumstanced that in their own interests they had better submit to recognised and rational methods of treatment, rather than to an irresponsible empiric.

"GIVING NATURE A CHANCE."

To the Editors of THE LANCET.

SIRS,—You allude to me by name in THE LANCET of Jan. 20th (p. 211), and I ask in common fairness to be allowed a word of protest against one sentence. You say, "It is cruelty thus to juggle with the hopes of the sick." The word "juggle" implies some trickery and unfairness. I venture to say that my conduct in expressing an opinion that a large proportion of the crippled children I saw were not incurable was at least honest. I may be wrong, but until some demonstration of error is forthcoming I protest against your charge of "cruelty" and "jugglery." I am, Sirs, your obedient servant,

Park-lane, W., Jan. 23rd, 1900. JOHN ATKINSON.

THE ARRANGEMENTS AT THE EXAMINATIONS OF THE CONJOINT BOARD.

To the Editors of THE LANCET.

SIRS,—I would venture to suggest that the arrangements in the Final College (Medicine) Examination should be so altered as not to keep the candidates an inordinate length of time in waiting for their cases. I myself, along with other students, had to remain in the waiting-room last Monday afternoon from 2.30—the hour given on the card—until nearly 3.40 before being called to the cases. All this was certainly not very conducive to a calm mental condition, especially as the only method of passing the time consisted in perusing one or two evening newspapers. The arrangements for the "vivâs" in the evening were much better, the candidate having only to wait five or ten minutes before being called. I am, Sirs, yours faithfully,

Jan. 23rd, 1900. GROWLER.

THE GIVING OF ANÆSTHETICS BY UNQUALIFIED PERSONS.

To the Editors of THE LANCET.

SIRS,—A friend of mine has written asking my advice and I should be obliged if you will give me your opinion in the matter. He is a chemist in a country village in Scotland, and the medical man there has lately been asking him to give chloroform in minor operations. He has done so in several cases but does not feel easy about it and wishes to know whether he ought to and what his position would be in the case of any accident happening with the anæsthetic. The medical man has assured him that he takes all responsibility, and that there is no difficulty in the matter. Will you kindly give me you opinion on the matter? Thanking you in anticipation,

I am, Sirs, yours faithfully,

Jan. 21st, 1900. R.

*** The medical man cannot assume the responsibility supposing "any accident happened." No anæsthetic should ever be administered by an unskilled person except under circumstances of extreme urgency.—ED. L.

INSECTS IN THE EXTERNAL AUDITORY MEATUS.

To the Editors of THE LANCET.

SIRS,—I think the account of the following case may be of interest to the members of the profession as showing the protective nature of the ceruminous exudation of the ear. In August, 1899, a patient came to me complaining that on the previous evening an insect had flown into the external auditory meatus of one ear. He had suffered for some little time afterwards from an intolerable "buzzing" noise in that ear. As he was out on a cycling expedition he got one of his companions to pour into the meatus some ordinary paraffin, but no insect could be detected. The patient tells me that from that time he gradually became more and more deaf on the side mentioned, but took no steps to remedy the inconvenience. A few days ago he began to suffer from pain, and, thinking there might be some wax impacted, he poked about with a pin, ultimately bringing out a mass of wax from the ear on examining which a large-sized moth was seen to be embedded in it, very distinctly preserved. He is now quite relieved from his deafness and looks on the "moth as somewhat of a" curiosity.

I am, Sirs, yours faithfully,

W. E. MAW, L.S.A. Lond.

Rawdon, via Leeds, Jan. 21st, 1900.

A DROLL VACANCY.

A CORRESPONDENT informs us that he recently inserted an advertisement in the press to the effect that as a doubly qualified locum tenent he would be prepared to accept a vacancy at the end of January. In reply to his advertisement he received the following remarkable letter the names and addresses in which we omit:—

Normanton

January 15th 1900.

Dear Sir

Hearing of a situation concluding to the Medical Staff. I write to you, Kind Sir wishing to fulfil that Profession. My Name is T —— F —— H —— living in the Township of Normanton and is well aquainted with the Head Doctor at Normanton Doctor M ——. I would be thankful to you if this letter suit. I am a Single Gentleman, and would do the very best I could to please you. I am 25 years of age. Hoping to hear from you soon,

I Remain

Your's Sincerely

Doctor H——.

Not the least funny part of "Doctor H——'s letter is that he considers himself to be a "Vacancy."

THE ANÆSTHETIST'S POSITION TOWARDS QUACK DENTISTRY.

THE *Birmingham Daily Mail* for Jan. 11th contains the following advertisement. As we do not find any medical man or dentist upon the Register bearing the name of Molar, we would suggest that the medical man associated with Molar as anæsthetist should cease from giving his services over the seed shop.

MOLAR'S

ARTIFICIAL TEETH

ON THE EASY PAYMENT SYSTEM,

20, HIGH STREET, BULL RING

(Four doors from New Street Corner),

A COMPLETE SET FOR ONE GUINEA.

A SINGLE TOOTH, 2s. 6d.

A PERFECT FIT GUARANTEED.

ANY SET of MOLAR'S ARTIFICIAL TEETH not giving full satisfaction or fulfilling their proper functions within three months of fitting will be REMADE FREE OF CHARGE.

ALL MOLAR'S ARTIFICIAL TEETH are REPAIRED FREE for 12 Months.

TO SUIT ANY MOUTH. ADVICE FREE.

ANÆSTHETICS BY MEDICAL MAN.

PAINLESS EXTRACTIONS BY GAS.

1s. 6d.

TEETH STOPPED CROWNED, & SCALED.

MOLAR'S,

20, HIGH STREET, BULL RING

(OVER THOMSON'S SEED SHOP).

HOURS, 10 TO 8 DAILY. SATURDAY, 10 TO 5.

BULLET WOUNDS AS REPRESENTED BY NEWS COMPOSITORS.

THE *British and Colonial Printer* of Jan. 5th, 1900, has an amusing notice of how a story may differ from the original narrative when it has had several independent and successive renderings. This, says our contemporary, "holds good, though in a somewhat different

e representation of Sir W. Mac Cormac's descrip-
let-wound in THE LANCET, as quoted by the
's contemporaries. The Globe of the 22nd inst.
cription and reproduces the eminent surgeon's
to size as possible, using for the purpose a good bold
of *two-line brevier*; when, however, the *Daily*
deals with the subject on the next day, lo! a *two-*
ap is taken! If the proportionate diminution goes on
of the paper decreases, we shall find that, like in the
all hardly recognise our old and original friend; and
wound will resolve itself into a 'full point,' and we
ously be led to believe that a modern bullet merely
in-prick."

F.C.S.M.

To the Editors of THE LANCET.

was called to visit a patient, aged 69 years, at 5 A.M.,
lay, the 11th inst., and found she had died. She had
ring, from pulmonary trouble for some time and was
with medicine by the man whose label is enclosed.
quest held on this case death was found to be due to natural

owing is a reproduction of the label referred to. The quantity
l hours for taking the dose are filled in in pencil.

1 or 2 table-spoonful to be taken every 2 or 4 hours.

J. O. PURDUE, F.C.S.M. LOND.

Member of the Magnetic and Botanic School of Safe Medicine, London, founded 1893.

All kinds of Medicinal and Herbal Preparations, kept in Stock.

ADVICE GRATIS DAILY.

REQUISITES FOR INVALIDS, FOR SALE OR HIRE.

7, GALT STREET, near Salmon Lane, LIMEHOUSE.

Formerly 5½ years Manager of the Medical Hall.

PUBLIC AND POOR-LAW DISPENSERS.

To the Editors of THE LANCET.

SIRS,—May I through the medium of your correspondence column ask any past or present Public or Poor-law dispenser who has not received a copy of the rules of the Public and Poor-law Dispensers' Association to communicate with me at the address below or to attend our next meeting on Jan. 31st, at 8 P.M., at St. Bride's Institute, Ludgate-circus, E.C. Thanking you in anticipation,

I am, Sirs, yours faithfully,
G. F. FORSTER, M.P.S.,
Honorary General Secretary Public and Poor-law Dispensers' Association.

c/o The Shuttleworth Club, Fye Foot-lane, Queen
Victoria-street, E.C., Jan. 22nd, 1900.

THE OPEN-AIR TREATMENT OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—Could you or any of your readers tell me where a patient (gentleman) in rather poor circumstances could obtain the open-air treatment for phthisis? Davos and other places of that standing seem too expensive, but I hear there is a society recently formed for assisting people to obtain the open-air treatment. Is this so? and if so, could anyone favour me with the address of the secretary?

I am, Sirs, yours faithfully,
W. R. K.

Jan. 23rd, 1900.

*** Lists of Institutions will be found in THE LANCET of Sept. 9th, 1899, p. 724, and Sept. 23rd, 1899, p. 851.—ED. L.

THE NÆVUS OF PATRIOTISM.

WE extract the following story from the *Cape Argus*, a paper published in Cape Town:—

SINGULAR FREAK OF NATURE.

A baby (girl) born lately in one of the suburbs has a distinct mark (strawberry colour) on the right shoulder. The mark is the facsimile of the British coat-of-arms. So distinct are the several outlines, &c., that the very features of the animals are visible, the tail, and especially the horn of the unicorn standing out prominently, but not quite as conspicuous as the crown. The father of this wee mite is naturally very proud of his offspring and prophesies great things for her future on account of this singular distinction. She no doubt will grow up a loyalist.

This is a distinct advance upon the old-fashioned strawberry mark, and in former times such an occurrence would have been taken as a portent of the assured success of the British army. In these unromantic days, however, it is probable that some matter-of-fact practitioner will propose the removal of the British coat-of-arms by electrolysis.

VOMITING OF PREGNANCY.

To the Editors of THE LANCET.

SIRS,—In reply to the query of "Obstet." in THE LANCET of Jan. 20th (p. 212), as to treatment of sickness in early pregnancy, I advise him to give twice daily before meals the following mixture: Liquid extract of ergot, five minims; water, half an ounce. I have seldom found it to fail after a few days in relieving, if not in entirely curing, the sickness. The same prescription, with the addition of nux vomica three minims, is often very useful in checking the sickness of the menstrual period.

I am, Sirs, yours faithfully,
A. GORDON PATERSON, M.D.

South Lodge, Ascot, Jan. 23rd, 1900.

Physician and Surgeon.—There is no law to prevent persons, however ignorant, from practising medicine or surgery at their own risk, provided that such persons do not use titles to imply that they are properly qualified members of the medical profession. The General Medical Council has no power over unqualified persons.

"Bartholomew."—Our correspondent's questions cannot be answered upon his brief description of the case and without a knowledge of the patient's pecuniary circumstances. We shall be happy to publish a fuller statement.

X. Y. Z.—We cannot give an opinion upon the very slight information supplied. If our correspondent will favour us with a full account of the circumstances we shall be able to advise him.

Cornstalk.—(1) Yes. (2) Notice should be sent only to patients whose names are on the books. (3) We think so. (4) Yes. (5) It depends on the usual custom in the locality.

R. W. W.—A notice of the preparation appeared in THE LANCET of July 7th, 1883, p. 18.

Mr. M.—Our correspondent is advised to inquire of his own medical attendant.

Mr. J. M. Burke.—Our correspondent had better apply to his dentist.

R. W. D.—We think the notification is in perfectly correct style.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

---

During the week marked copies of the following newspapers have been received *Daily Express (Dublin), Eastern Morning News, Darwen News, Kent Argus, Weekly News (Broadstairs), Sussex Daily News, Birmingham Daily Post, Leicester Daily Post, New York Sun, Burton Mail, Lancashire Daily Post, Nottingham Daily Guardian, Liverpool Daily Post, Scotsman, Western Morning News, Yorkshire Post, Times of India, Pioneer Mail, Bradford Observer, Gainsborough Leader, Daily Messenger (Paris), Glasgow Herald, Builder, Brighton Gazette, Architect, Citizen, Manchester Guardian, Bristol Mercury, Morning Herald, Devizes Advertiser, Leamington News, Herald, Cape Argus (Cape Town), Leeds Mercury, Preston Herald, Ayrshire Post, Dewsbury Reporter, Rangoon Times, Victoria Daily Times, The Australian, United Service Gazette, The Cigarette World and Tobacco News, Oxford Times, The Dairy, Peterborough Express, Sanitary Record, Hertfordshire Mercury, Bolton Daily Chronicle, Reading Mercury, City Press, Local Government Chronicle, Mining Journal, Rangoon Gazette, Surrey Advertiser, Local Government Journal, Le Courrier de la Presse, Bury Free Press, English Gazette (Paris), Inventions, Swindon Advertiser, Bicester Herald, Willesden Chronicle, &c., &c.*

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index to Vol II. of 1899, which was completed with the issue of Dec 30th, and the Title page to the Volume, were given in THE LANCET of Jan 6th

VOLUMES AND CASES

VOLUMES for the second half of the year 1899 are now ready. Bound in cloth, gilt lettered, price 18*s*, carriage extra

Cases for binding the half year's numbers are also ready Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground, should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, [illegible] STRAND, LONDON, ENGLAND

Presidential Address

THE VALUE OF EYE SYMPTOMS IN THE DIAGNOSIS OF GENERAL DISEASES.

Delivered before the Harveian Society on Jan. 18th, 1900.

By HENRY E. JULER, F.R.C.S. Eng.,
OPHTHALMIC SURGEON TO ST. MARY'S HOSPITAL AND CONSULTING OPHTHALMIC SURGEON TO THE LONDON LOCK HOSPITAL.

GENTLEMEN,—For upwards of 50 years it has been the custom of this Society for the out-going President to deliver an address at this annual general meeting. The actual rule is that he shall expatiate on the objects and aims of the Society, illustrating its great usefulness as a scientific and practical body by enlarging upon the works begun, continued, and ended during the past year of office. Fashion, however, changes, and I am informed by our able honorary secretaries that this rule is no longer regarded, but that the President is expected to give an address upon some subject chosen by himself and it is hinted, rather than spoken outright, that this address should not be too long nor too short; that it should be medically scientific, and, above all things, interesting. Well, gentlemen, in theory it seems to be quite an easy and pleasant task, but in practice the difficulties become more and more evident as the annual meeting approaches. On my part I promise that it shall not be too long, but on your part I fear that it may not be considered either too short or too interesting.

It has occurred to me to address you upon the value of eye symptoms in the diagnosis of general diseases.

The eye is so intimately connected with the other organs and structures of the body that it must necessarily follow that it would sympathise, not only with its fellow eye, but with many of those structures of whose nature it so intimately partakes.

The optic nerve comes forward and expands into the retina which may almost be regarded as a diminutive brain, having its ganglion cells, nerve fibres, and neuroglia; whilst light-sense, form-sense, and colour-sense are all conveyed to the various nerve-centres of the brain and thence to the various and most remote parts of the body. So sensitive is the eye to all nerve impressions that in deep anæsthesia, as from chloroform, the pupil will dilate by simple pinching of the arm. On the other hand, if a hot iron is made to touch a person's arm he instinctively not only pulls his arm away but he directs his eyes in the direction of the burning instrument. Varied movements of the body are instantly brought about by direct vision.

The iris, ciliary body, and choroid are in intimate connexion with the blood-vessels of the brain, the liver, and other parts of the body. It is easy to understand how sarcoma, glioma, and other malignant growths might be and are conveyed by these channels from the eye to the brain and the liver and other parts of the body. The eye contains a complete lymphatic system consisting of the anterior chamber, the canal of Schlemm, and other lymph spaces within the choroid and outside the eye but within the capsule of Tenon. These communicate most freely, not only with the other eye and the intracranial cavities, but with the lymphatics of the nose and face in the immediate vicinity of the orbit. The extra- and intra-ocular muscles of the eye, with the numerous and important nerves supplying them, constitute one of the most important diagnostic studies in medical science.

I feel, therefore, that no apology will be required from me if I bring before your notice to-night a few remarks illustrative of, in the first place, the great value of eye symptoms as a means of diagnosis in general disease, and, in the second place, of some mistakes which may be made by practitioners even of the first rank in our profession.

Take, for instance, the conjunctiva. This delicate membrane often becomes inflamed, it looks red and swollen, and may give off a discharge. In the majority of cases this is simply a local affection and can be cured in a short time. Such, however, is not always the case, the local trouble may be indicative of other diseases in the system. I well remember being called by a medical man to see a patient about 65 years of age who had a purulent discharge from both eyes, the eyelids were swollen, the conjunctivæ were infiltrated, and the corneæ were cloudy and had lost the epithelium from a great portion of their central areas. Not only were the eyes affected, but the skin was red and irritable, extending from the eyelids upwards over the scalp and downwards over the face and neck to the chest and abdomen. I was much concerned at the severity of the case, especially as I had never seen such extensive dermatitis in any case of ophthalmia before. Before giving an opinion I examined the discharges microscopically and found them to be teeming with colonies of gonococci. I told the practitioner at once that his patient was suffering from gonorrhœal ophthalmia and that he was in the greatest danger of blindness. The source of contagion could not at first be traced as the patient himself was free from urethral gonorrhœa. It turned out, however, that he was accustomed to take a warm bath at night and that one of his sons used the same bath and the same towel as he did. This son had urethral gonorrhœa, and thus the study of an eye case led to the discovery of a similar disease in another patient.

In a second case I was called by a medical man to see his son who had a purulent discharge, swelling, and pain in each eye. The corneæ were both intact. His father, mother, and eldest sister were all in attendance upon this patient, each taking a turn at bathing and cleansing his eyes and so exposing themselves to great danger of inoculation. Microscopic examination proved gonococci and private conversation with the patient revealed urethral gonorrhœa. The patient under proper treatment and skilled nursing made a good recovery and fortunately the near relatives all escaped gonorrhœal ophthalmia.

A third case was the reverse of these. It was that of a man who stated that on the previous night his right eye had become red, swollen, and had a muco-purulent discharge. He said he knew the fearful nature of gonorrhœal ophthalmia, because a friend of his had suffered from it and was now quite blind. He further volunteered the statement that he was the subject of urethral gonorrhœa and gave me other details to account for his mental perturbation. I told him I did not think that it was gonorrhœal ophthalmia because the discharge was shreddy and watery and not liquid pus and that I would examine it on my return home and would send him a report that evening. The joy he showed on being told that the discharge showed no sign of gonorrhœal ophthalmia can scarcely be imagined. His first visit was on Saturday and by Monday the eye was practically cured.

I could quote many other cases of a similar nature, but these will suffice to show the great importance of examining the discharges in all cases of severe ophthalmia either in adults or in new-born children, for if the gonococcus is present there is always great danger, and if absent the patient is sure to get well under ordinary treatment.

Gonorrhœa has been shown of late years to be much more extensive in its ravages upon the general system than was formerly supposed. Urethral gonorrhœa may form metastatic disease of the eye as well as of the joints. In a recent paper by Mr. John Griffith read before the Ophthalmological Society he called attention to the fact that gonorrhœa is a frequent cause of iritis, and that iritis thus caused may occur many years after the urethritis, and is similar in character to that found in articular rheumatism. It usually occurs in males, generally in both eyes and often recurs with relapses of gonorrhœa or alternates with attacks on the joints.

Another general disease affecting the eye which may come first to the ophthalmic surgeon is diphtheria. This is fortunately much more rare than gonorrhœal ophthalmia; indeed, it is the rarity of its occurrence which puts us off our guard.

I well remember the case of a child who was brought to me by Dr. Horace Manders. The child's eyes were both red, the conjunctivæ were swollen, there was c
lacrymation, the corneæ were hazy, and their
almost fluffy in appearance, but the fluff did.
off with the tears. I was much interested an
owing to this cloudiness of the cornea, will be
not white like a diphtheritic exudation. I[illegible]ed.
was a form of purulent ophthalmia and wence o

it to be so serious that, by Dr. Manders's request, I took the case under my entire charge and treated it in a nursing home. I visited the child twice daily and once daily administered chloroform so as to examine the eyes thoroughly and applied nitrate of silver to the lids. To my horror, however, it became worse and worse, the corneæ becoming greyish white and false membranes forming on the palpebral conjunctivæ. On the fourth day, whilst the child was crying and spluttering in my face, I noticed patches of membrane on the tongue and fauces and then I realised to what danger I had exposed not only myself but the nurses and even the nursing home in charge of the case. A careful examination of the discharges from the eye in this case with cultivations from the same would have discovered the dumb-bell bacillus and so have saved my reputation. It might also have saved the eyes of the child, which were both lost. This case occurred some years ago before we were alive to the importance of bacteriological examinations and cultures.

Mr. W. H. H Jessop has recorded two cases of diphtheritic conjunctivitis quickly cured by injections of Klein's antitoxin. In both cases the Klebs-Löffler bacilli were discovered in the membrane and were cultivated.

Another class of diphtheritic cases constantly occurring in ophthalmic practice is illustrated by the following. A man, aged 21 years, came to St. Mary's Hospital in 1896 complaining that he could not see properly. His difficulty in reading was very great. He had suffered from "ulcerated throat" about five weeks before and had stayed in bed two weeks. Two weeks later he tried to resume work but found the difficulty just described. Before the illness he could see fairly well. His medical man had said that the sore-throat was not diphtheritic, but in my opinion this was a typical case of paresis of the ciliary muscle causing failure of accommodation. Had proper examinations and cultivations been made in this case the diagnosis might have been established.

This characteristic paresis often follows diphtheria of all parts of the body as in the conjunctiva, vulva, and wounds, but it is most frequent after pharyngeal attacks. It generally begins about two weeks after the attack has run its course and lasts from four to eight weeks. It is always bilateral and the sphincter pupillæ are seldom affected. It is frequently accompanied by a nasal twang of the voice and difficulty in swallowing, so that on attempting to drink the fluid will pass up the posterior nares and out through the nostrils. The extra-ocular muscles are occasionally affected by diphtheria, with or without the loss of accommodation, and cause further visual trouble by the diplopia thus produced.

Syphilis is so frequently found in the eye that I can only touch upon those cases which are often seen first by the ophthalmic surgeon. In acquired syphilis the eye may be the point of entrance of the infection. This may be brought about by the agency of the finger, the tongue, or the lips. Young infants and children run a risk of inoculation when kissed by infected persons, and indiscriminate kissing is evidently a pernicious habit.

In my recent Harveian lectures I quoted cases of chancre of the eyelids. These involve, with very few exceptions, the palpebral conjunctiva Usually they are situated at the lid margins, but they may start at the caruncle or at the other canthus. The clinical course of these chancres does not materially differ from those elsewhere. The amount of local reaction varies greatly. The pre-auricular gland is always enlarged, firm, and painless, and it is not tender unless it is manipulated roughly. This absence of tenderness has a diagnostic significance and the diagnosis of primary syphilitic sores in this region constitutes one of the most interesting problems in surgery. It may be mistaken for rodent ulcer, tertiary syphilitic ulcer, epithelioma, and lupus, chalazion, hordeolum, and tuberculous ulcer of the palpebral conjunctiva

Chancre of the eyelid is, as I have just said, always accompanied by enlargement and induration of the pre-auricular gland and sometimes of the submaxillary gland also. The presence, therefore, of glandular swelling will help to exclude many of the above affections. Thus rodent ulcer, [illegible] syphilitic ulcer, lupus, and, in most instances, chalazio[illegible] [illegible] be excluded, for in all these the pre-au[illegible] unaffected. In epithelioma it is different, [illegible] [illegible]cted as in other regions, yet [illegible] removed for suspected rodent [illegible] to be epithelioma without [illegible] pre-auricular gland. The [illegible] [illegible]us ulcer has caused [illegible] [illegible]ncre would have healed spontaneously and the sufferer would be halfway through the secondary stage of syphilis. With suppurating chalazion and suppurating styes the gland may be affected, but in such cases it is much swollen painful, very tender, and the skin over it is red and œdematous. It is, in fact, an acute adenitis and easily distinguished from a chronic enlargement. Now by a process of exclusion only one ulcer is left, the tuberculous ulcer of the conjunctiva, which is sufficiently rare to have been much overlooked in literature. This is the only ulcer that is liable to be mistaken for a chancre. The pre-auricular gland is firm and swollen and the ulcer is circular or oval and saucer-shaped. Be suspicious if there is no induration at the base of the ulcer. A tuberculous ulcer, I have learnt from experience, is never indurated. I could, if time permitted, quote two cases of tuberculous ulcer of the eyelids, one of which terminated fatally in tuberculous meningitis and the other in general tuberculosis.

It is well, therefore, not to commence the constitutional treatment of suspected chancre of the eyelid until the diagnosis is confirmed by the secondary manifestations of syphilis, for the use of mercury, which is so very beneficial in the syphilitic, is liable to act injuriously in the tuberculous cases.

Another large class of cases resulting from acquired syphilis is that of syphilitic iritis. This is probably most common *in men, but the cases I refer to now as coming in* the first place to the ophthalmic surgeon are mostly those of women of all ages, single, married, and widowed. I have seen them in patients aged from 15 to 65 years and they are mostly apparently unconscious of the presence of any systemic infectious disease. At least they do not appear to know that the syphilitic affection is the cause of the eye trouble. They come complaining of dimness of vision, the iris is dull and infiltrated, the pupil is fixed and irregular, the circumcorneal zone is injected. and there is little or no pain. On looking for collateral signs there is usually a copious skin rash, the hair comes off, the throat is sore wit[illegible]us patches, and by ingenious questions on the part [illegible]urgeon a history of chancre on the genitals may [illegible] elicited without giving alarm, offence, or even susp[illegible] to the patient. I could quote scores of such cases an[illegible] [illegible]now of no cases of secondary syphilis which more clear[illegible] [illegible]lustrate the value of mercurial treatment in producing ra[illegible] recovery. In dealing with such cases great tact is req[illegible]ed on the part of the practitioner to avoid the disturbance of domestic happiness. Our first duty is to cure the patient and, in my opinion, we are not called upon to incriminate other persons who may or may not belong to the domestic circle.

Interstitial keratitis, again, is another phase of eye troubles arising occasionally from acquired syphilis and more often, indeed, in the great majority of cases, from the inherited form of this disease. I do not deny that interstitial keratitis may result from other than syphilitic causes, but I am convinced that the great bulk of cases occurring in this country are due to this cause.

Well, these generally come first to the ophthalmic surgeon. We know them at once by the steamy, deep-seated cloudiness of the cornea which varies, of course, with the stage of the affection and with the severity of the infection. It generally appears in children about the age of puberty, although it may occur earlier or later in life; when coming on later it is usually in the form of a relapse.

The proof of inherited syphilis is not always easily established. It is best to adopt a sort of Sherlock Holmes's method of observation. Direct questioning is often difficult, not to say embarrassing both to the medical man and to the parents of the child. Neither parent would like to admit that the cause of the child's disease had originated in his or her own person. The father will privately admit that he had syphilis many years ago, a considerable time before marriage. The mother will gladly tell about premature *labours, children born dead, previous miscarriages,* skin rash, sore throat, and so forth.

The collateral symptoms of inherited syphilis occurring in the patient are frequently to be traced, but they necessarily vary, as I have said, with the dose of the disease which has fallen to the lot of this particular child. The question of the Sherlock Holmes's method of observation has recently been commented upon in medical literature, and I must take this opportunity of commending it most cordially so long as it is used for detection and not for exposure. In this particular affection, for instance, the medical Sherlock, with the previous assistance and coöperation of the maiden aunt, the mother-in law, or some other person who knew all the family history, might easily address his patient in the following strain. We will suppose that this child was not the first, but the second, affected by the disease. He might say: "Your eldest sister is deaf; she is very ugly and not nearly so well developed as you are; her eyes were once considerably worse than yours and her sight is still defective, her upper front teeth are notched, the bridge of her nose is sunken, and she has a *café au lait* complexion. Your younger brother is quite well, his sight and hearing are good, he is even better-looking than you are, and he is not deaf. Your mother was not well after her marriage, her hair came off, she had a rash all over her body, and a sore-throat. She had a little boy who was born dead. Your father, well, I could say something about your father, but he is still a big and powerful man, and so perhaps I had better not."

No doubt Dr. Conan Doyle's method is an excellent one, but I am sure he would agree with me that it should be used exclusively for observation and the better treatment of our patients, but never for their exposure.

Another infective disease in which we are often consulted is influenza. Considering the myriad of cases that are said to occur of this disease it is surprising that more eye troubles have not been recorded. Nevertheless, many sequelæ do occur and that apparently in direct proportion to the severity of the previous attack. A few years ago a medical friend of mine sent me quite an urgent message saying, "Dear Juler, my wife has developed a most fearful squint. Do come and operate at once." His wife was a beautiful lady, and he, poor man, was much disconcerted. She had recently sustained a severe influenzal attack in which the temperature had been over 105° F. with some basic pneumonia. The case was only one of paresis of the external rectus muscle causing internal strabismus. My friend had the pleasure of seeing this squint quite disappear in the course of a few weeks without the necessity of the proposed operation.

Quite recently I was called to a case of acute glaucoma occurring in a lady about 50 years of age. There appeared to be no other cause than recent influenza. I performed iridectomy and the operation seems to have been as effective here as in ordinary cases of acute glaucoma. Only one eye was attacked.

We constantly see cases of hyperæmia of the conjunctiva with or without discharge. Paresis of accommodation is frequent though less severe than that following diphtheria although it seems to take longer to recover. Cases of embolism of the arteria centralis retinæ are recorded by Hosch and Coppez. Pronounced optic neuritis and neuro-retinitis single and double have been reported by Cross, Hartridge, Snell, and many others, including myself. The fundus presents varied appearances, in many cases seeming like an ordinary optic neuritis, in others presenting small brilliant white dots between the optic disc and the macula. These dots will sometimes disappear. The defect of vision varies, but in some cases the patient becomes totally blind.

Before going further I should like to dwell a little upon the importance of the ophthalmoscope as a means of diagnosis. The great charm, at least to my mind, of ophthalmic practice is the precise and definite nature of the work. We can in the great majority of cases coming before us give a definite diagnosis, a definite line of treatment, and a definite prognosis. This is undoubtedly due in a large measure to the proper and skilful use of the ophthalmoscope. Unfortunately I fear that many practitioners do not keep up the use of this instrument All must have some knowledge of its use, for nowadays a student cannot present himself for examination even for the Membership of the Royal College of Surgeons without a certificate of having done ophthalmic work. Still, there is a holding back in the use of this most helpful instrument, although to my mind nothing is so simple and easy. By retinoscopy, or the shadow-test, we can in a few minutes find out not only the quality of an error of refraction but we can estimate its quantity with the greatest accuracy. By the direct method of ophthalmoscopic examination we can scan the retina, the optic nerve, and the choroid. A few drops of *homatropine* hydro-bromate instilled into the palpebral sac about half an hour before the examination renders this quite a simple matter which can be learned from any modern text-book.

One of the best instances of its use is, I think, in the detection of malingerers. Although the conscription is not in force in the British empire at the present time yet we find many persons who believe or pretend that they cannot see. They generally complain of one eye only. Many of this class of patient belong to the school girl type, between the ages of 10 and 18 years. We frequently see them both in hospital and in private practice. A girl is brought by her anxious mother, who states that the girl cannot see with one eye. We examine the pupils and find them both equal, active to light, and normal in size. By retinoscopy we find there is no ametropia such as would cause blindness. By the direct ophthalmoscopic examination we find the fundus absolutely normal. The room has been darkened for this examination and the patient cannot very well see what we are manipulating An empty spectacle frame capable of holding lenses is placed upon the patient's face and she is told to read illuminated test type in the corner of this dark room, then, both eyes being open, a strong convex lens is placed in front of one of the eyes so as to obscure its vision, and she is told to read again, then the other eye is treated in the same way She does not know at the time that this glass obscures the vision. This is generally sufficient to confuse the patient to such a degree that she will read all the letters with either eye, not being quite sure with which eye she is actually reading. Having thus proved, to our own satisfaction, that the patient can read with either eye, we resort to Snellen's coloured test-types which are red and green. We also place a red and green glass in front of each eye respectively, and this isolates the eyes so that one eye can only read red and the other only green letters. Now she is told to read and she will at once read both the red and green letters, showing that both eyes are working and that she has been mistaken about her sight.

In these young people there seems to be no definite motive for malingering, and they really seem to think that they cannot see. I never accuse them of untruthfulness, nor do I think it well to tell even the parent that the young lady is untruthful. The parent is greatly distressed and often not a little indignant. It is, I think, better to be silent and to advise the parent to withdraw all apparent sympathy. The condition is no doubt an early phase of hysteria, although very different from actual hysterical amblyopia

Older women come with the same kind of complaint. In men the motive is often more apparent, but even then they fall into the same trap by the mystifying treatment I have just described and by the time we come to the coloured types they will read the red and green letters indiscriminately. I have recently had several cases where by the use of the ophthalmoscope and the coloured types just mentioned I easily proved to my own satisfaction that I was dealing with a malingerer, and I could mention many instances showing the great value of the ophthalmoscope in forming a correct diagnosis where it would have been difficult to do so without a knowledge of its use. If the instrument is so useful in this trivial subject of malingering how much more valuable must it be in the detection of actual disease.

Take, for instance, renal diseases. Nothing is more common in either hospital or private practice than the discovery of albuminuric retinitis The patient may be quite unaware of any trouble beyond defective sight and the ophthalmoscope demonstrates the existence of slight optic neuritis, white spots around the macula, and hæmorrhages scattered over the fundus of one or both eyes. The urine is examined and found to contain albumin and casts galore. These albuminuric affections of the retina are occasionally found in all forms of nephritis. They are most frequent in the later stages of contracted kidney, and when found in such cases they indicate not only a loss of vision but also a probable loss of life in the near future

Lastly, eye symptoms are of the greatest possible value in the diagnosis of diseases of the nervous system, intra-cranial and otherwise; but, alas, my time has expired and I should require a longer period for the development of this aspect of ophthalmology.

Gentlemen, I hope I have not wearied you, and before I finish this expiring effort of my year of office let me thank you for the honour of having been elected to act as your president for the past year.

A Clinical Lecture

ON

SOME COMPLICATIONS FOLLOWING ON INJURIES ABOUT THE ELBOW-JOINT AND THEIR TREATMENT.

Delivered at the Leeds Infirmary on Nov. 14th, 1899,

BY H. LITTLEWOOD, F.R.C.S. ENG.,

SURGEON TO THE LEEDS INFIRMARY; LECTURER IN PRACTICAL AND OPERATIVE SURGERY IN THE YORKSHIRE COLLEGE (VICTORIA UNIVERSITY).

GENTLEMEN,—There is one complication sometimes following on injuries about the elbow-joint which I want more particularly to discuss to-day, the more so as there is practically no mention of it in the ordinary surgical text-books. I am inclined to think that it is not so rare a complication as it is sometimes thought to be, as I have seen it in at least ten cases during the past 12 years. I have, however, discussed the condition with some hospital surgeons of considerable experience, who tell me that they have never seen a case. Here and there in the medical journals cases have been described, their pathology discussed, and various plans of treatment recommended. During the last 12 months two cases have come under my care and it is from a study of these that I shall base my remarks as to the pathology of the condition and advocate the treatment which I carried out.

The deformity is this, that when the wrist is extended then the inter-phalangeal joints of the fingers and thumb are strongly flexed, so that the tips of the fingers touch the lower part of the palm, and no reasonable amount of force appears to be capable of straightening them (see Fig. 1, A and B), but

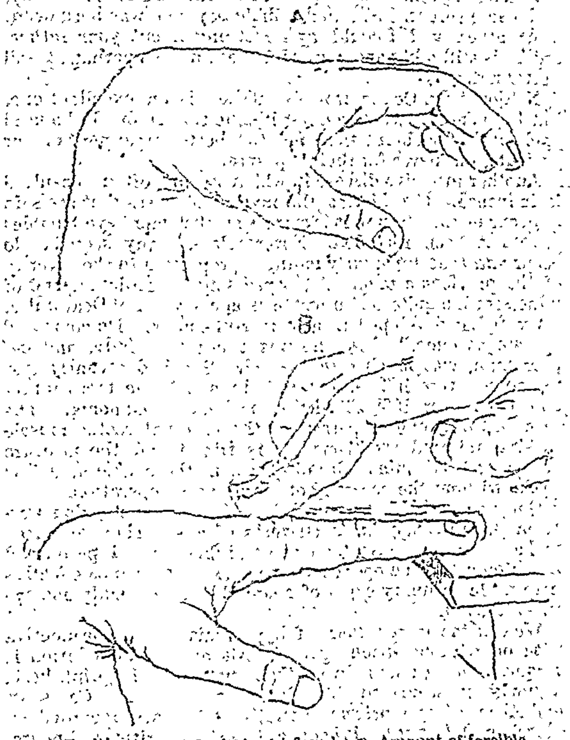
oint is flexed to a right angle then the £can be easily extended (see Fig. 2, A ed the deformity may be thought the nerves, probably the musculo- ll not account for the deformity, ses one or more of the nerves may was thought that there was some ulnar anæsthesia. You are all familiar with the characteristic deformities and anæsthetic areas associated with musculo-spiral, ulnar, and median paralysis, and none of these are like the condition which I refer to. The deformity appears always to occur in children after some severe injury about the elbow-joint, and generally after a fracture separation of the lower humeral epiphysis. I have once seen it after a dislocation of both bones of the forearm backwards. The cause of the deformity is, I believe, primarily in the muscular portions of the flexor muscles of the forearm. If the histories of these cases are carefully gone into it will be found that the injuries have been severe and that the flexor muscles have been torn, possibly by the displacement of the forearm backwards with the lower end of the humerus. The torn muscle is replaced by fibrous tissue, and this, contracting, is, I believe, responsible for the deformity. A lump varying in size can be felt in the flexor muscles in the upper third of the forearm, and it has been present in all the cases which I have seen. It is a well-recognised condition in the sterno-mastoid muscle. A swelling is found in about the middle of the muscle soon after birth, which is thought to be due to a tearing of its fibres during parturition; this sometimes produces wry-neck.

FIG. 2.

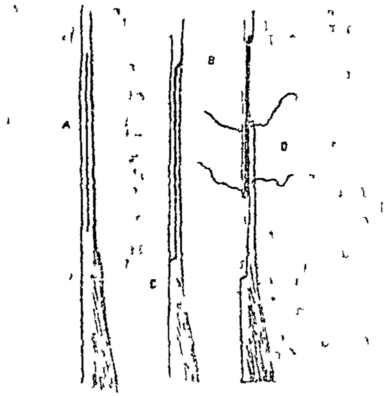


A, Position assumed with wrist flexed. B, Amount of forcible extension possible with wrist flexed.

I *do not* believe that splint-pressure has anything to do with the production of the deformity, although I am well aware that in most cases a sore—pressure-sore—is present; *but this is not always so, for in* Case 1 no abrasion of any kind was present and in Case 2 a sore formed but was on the extensor surface of the forearm. I am especially laying *stress on this point as it has* given rise to one theory—that the contraction is due to a secondary inflammation extending to the muscles from the splint-sore. That explanation clearly will not account for Case 1 in which there was no sore of any kind, and in Case 2 the sore was on the back of the forearm. One would imagine that any inflammation extending from this sore would have involved the extensor muscles and produced a hyper-extension of the wrist instead of involving the flexor muscles. For these reasons I am inclined to think that the pressure-sores are not causally related to the deformity; they may, however, be taken as some index of the amount of laceration of the soft parts at the time of the injury, producing a great amount of effusion which increases in amount after the application of splints Probably the effusion of blood into the skin and subcutaneous tissues renders them anæsthetic, acting in the same way as a hypodermic injection of water, and this may explain why a large sore may form and yet the patient will not complain of any pain, and on this account it is very important to examine the limb most carefully at short intervals, there is practically no fear of non union of the fracture If a splint sore forms you will very rightly have to bear the blame, and should unfortunately, contraction of the flexor muscles follow the friends of the patient will have no doubt that the result is due to tight splints In some of the cases pronation is limited and in others there is deformity about the lower end of the humerus the most serious being the presence of a mass of bone at the inner side preventing flexion of the elbow The removal of this mass generally produces satisfactory results Can anything be done to prevent this contraction? Of this I am doubtful If during the treatment, whatever method is adopted, any contraction of the fingers be noticed possibly the flexion contraction might be avoided by putting the arm in a straight anterior arm splint reaching to just above the bend of the elbow and posterior rectangular splint extending to the tips of the fingers, so that the fingers could be fixed in the extended position It would certainly be worth trying In one very slight case which I saw some time ago frequent massage greatly improved the condition I unfortunately lost sight of the patient, so I do not know what was the final result I will now describe to you the plan of treatment which I adopted in my two cases and then read brief notes of them

The parts having been made aseptic a tourniquet is placed on the arm and the forearm is held in the position of supination An incision about four inches long is now made in the middle line, beginning at the wrist and the skin is reflected The superficial flexor tendons are exposed and divided in the following manner A scalpel is thrust into the middle of the tendon and it is divided in the longitudinal direction for about one and a half inches (see Fig 3, A) At the lower part of this incision a transverse division of the tendon is made in an outward direction (see Fig 3, B), and at the upper part of the longitudinal slit a similar division is made directly inwards (see Fig 3 C) In this way the tendons are completely divided and the necessary lengthening can be obtained by sliding the split portions and suturing (see Fig 3, D) The exact amount of lengthening is determined by the ability fully to extend the fingers with the wrist in the extended position The superficial tendons after division are united with long threads of fine silk so they can be held apart and can be easily recognised for the final suture The deep tendons are now divided in the same way, the split portions sliding on each other to obtain the required increase of length and are at once sutured in two places with fine silk (see Fig 3 D) All the deep tendons having been divided, lengthened, and sutured, the superficial tendons are then sutured in the same way No vessels are ligatured The wound is closed with silkworm gut and a uniform firm wool and gauze dressing is applied from the fingers to the elbows, the fingers and wrist being placed in the extended position and the fingers separated by small pieces of wool, and only the tips of the fingers being exposed The tourniquet is then removed The operation takes about one and a half hours This form of dressing is sometimes painful for the first 24 hours If there is pain a small dose of opium or morphia should be given

FIG 3



Method of lengthening tendons

CASE 1—The patient a girl, aged eight years, was admitted to the Leeds Infirmary on Nov 17th, 1898 Four months before admission she had a fracture separation of the lower end of the humerus, with a good deal of swelling of the parts It was put up in an internal rectangular splint for four or five weeks When the splint was taken off it was noticed that the fingers were contracted and afterwards the contraction gradually increased There was some limitation of movement of the elbow joint, it could not be completely extended and could be flexed only to about a right angle Flexion was limited by a bony prominence at the inner side of the lower end of the humerus When the wrist was extended the inter phalangeal joints of the fingers and thumb were firmly flexed, the tips of the fingers touching the palm and the flexed thumb resting against the outer side of the flexed forefinger With the wrist in the extended position it was impossible to get any extension of the fingers If, however, the wrist joint were flexed then the fingers could be easily and completely extended. There were no cicatrices on the forearm the skin being perfectly normal At the upper third of the forearm in the flexor aspect a thickened mass could be felt in the substance of the muscles It was thought that there was some loss of sensation in the ring finger and the little finger

The operation already described was performed on Dec 5th, 1898 All the flexor tendons being lengthened about an inch a firm uniform antiseptic dressing of gauze and wool was applied from the fingers to the elbow, the fingers and wrist being extended The wound when dressed on Jan 1st, 1899, had quite healed and the silkworm gut sutures were removed The patient left the infirmary on March 30th, 1899 After leaving off the dressings for a few days it was found that there was some tendency to slight contraction of the sutured tendons To prevent this the limb was well rubbed and massaged and a back splint was worn for two or three hours every day The patient's condition greatly improved before leaving the infirmary, so that she could do some knitting The parents have persevered with the rubbing and she has now a very useful hand

CASE 2—A girl, aged six years, was admitted to the Leeds Infirmary on Jan 7th 1899 In May, 1898, the patient fell from a ladder and sustained a severe fracture about the left elbow joint and a fracture of both bones of the forearm The forearm was greatly swollen and the fractures were with *difficulty* kept in position A splint-sore formed about the middle of the back of the forearm, the condition was very similar to that in Case 1 The contraction, however, of the flexor tendons was more marked, so that when the wrist was flexed the fingers could not be completely extended Eight months had elapsed from the time of the accident Both fractures had united and the movements of the elbow joint were good The lump in the muscular part of the flexors was well marked

The operation was performed on Jan 9th, 1899 All the tendons with the exception of the flexor carpi ulnaris were divided, lengthened about an inch, and sutured Similar dressings to those used in Case 1 were employed. The wound was dressed on Feb 2nd; it had healed and the stitches were removed Daily massage was employed The patient left the infirmary on March 30th, 1899 The fingers were then quite straight and she had some power of flexion The condition is now greatly improved, and although at the present time the result is not as good as was the result in Case 1 yet I have very little doubt that ultimately the patient will have a very useful hand In both of these cases the nerves which were exposed, appeared to be healthy

In THE LANCET of March 12th 1898, p 722 Mr Raymond Johnson described a case of this kind in which he improved the condition somewhat by removing a portion of the radius and ulna Unfortunately he did not obtain bony union Mr Lawford Knaggs has kindly drawn my attention to a very instructive lecture in the *Guy's Hospital Gazette* for October 1898, by Mr Davies Colley on a similar case which he had had under his care and in which he first divided the muscles and got some improvement and later divided all the flexor tendons about one and a half inches above the upper border of the hand, the result being that the child's fingers were straight but could not be flexed.

The plan of treatment which I have described appears to me to be rational and from what I can gather from the description of other cases the results which I obtained will compare favourably with those obtained by other methods. I wish to thank my late house surgeon, Mr. Frank Talbot, for his help at the operations, for his care in the after-treatment of the cases, and for the drawings which he has made for me to illustrate this lecture.

DAY-TERRORS (PAVOR DIURNUS) IN CHILDREN.

By GEORGE F. STILL, M.A., M.D. Cantab., M.R.C.P. Lond.,

ASSISTANT PHYSICIAN FOR DISEASES OF CHILDREN, KING'S COLLEGE HOSPITAL; ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

THE occurrence of day-terrors in children has received but little attention. Much has been written about night-terrors, for these are extremely common; but it would seem that the similar but much less common attacks which occur in the waking condition during the day have scarcely been noticed by English writers. Henoch[1] in the fourth edition of his lectures alludes to their occurrence by a brief note of two cases, but so far as I can ascertain no others have been recorded with the exception of two cases of somewhat different character described under this name by Dr. L. G. Guthrie. Two cases of pavor diurnus, and a third probably of the same nature, have recently been under my care and, as will be seen, they closely resemble the condition described by Henoch.

Case 1.—A boy, about six and a half years of age, about four years ago had night terrors which continued to occur, but with decreasing frequency, until seven months ago, when they ceased. Three months ago he awoke one night at 11 P.M., and although he was wide awake he seemed terrified, clutched at his mother, and said that he was afraid of the trains (which run near the house, but of which he had never shown the least fear before). Similar attacks occurred on several nights subsequently about the same time, the child being wide awake on each occasion. Two months ago, after having one of these attacks on the previous night, he began screaming in fright one morning at 8 A.M., but without knowing why, and during that day he had several similar attacks. After this he had many attacks both day and night. They occurred at any time of day. Often the boy would suddenly stop in the middle of his play, look terrified, and rush to his mother screaming. Sometimes he says he hears something which frightens him; sometimes he hears an imaginary person coming up the stairs whom, however, he is unable to describe; and sometimes he cannot explain why he is frightened. During these attacks he always seems to recognise people about him and there are no visual hallucinations. His face does not change colour during the attack. The whole duration of the terror is not more than half a minute. The child is said to be "terribly excitable." He is spare, with bright intelligent face, very quick of apprehension, talks in an eager excited way about his toys and games, and is obviously a child of very "nervous temperament." He is pale, and the mother says he has been getting thinner ever since the attacks began three months ago. As an infant he never had convulsions, and beyond measles and the night-terrors mentioned above he has had no other illness. He complained of headache once three months ago but not since. The family history showed acute rheumatism in the mother and the maternal grandmother, but no fits or neuroses of any kind.

Case 2.—A boy, aged three years, for the last six weeks has had sudden attacks of screaming with fright, occurring often many times in a day. The attacks occur at any time of the day. Whilst sitting quietly with the rest of the family or busy at his play he will suddenly begin to scream, turn pale, and look "strange about the eyes"; he rushes to his mother and hides his face in her lap saying that he is frightened. Sometimes he says that "somebody is coming after him," but he cannot describe his imaginary pursuer nor is it clear whether the hallucination is visual or auditory. The attacks last from two to three minutes. He has had night-terrors with visual hallucinations for some weeks past and is "a very excitable child." He is easily frightened by trivial things—for example, on crossing a railway bridge a few days ago he saw the smoke of a train and screamed with fright. He easily becomes passionate if thwarted. He has never had convulsions. The child is fairly nourished, quick, and intelligent, perhaps precocious; he is shy, but when this is overcome he talks in the rapid, eager fashion of an excitable child. There is a little puffiness about the lower eyelids suggesting some intestinal catarrh; the bowels are costive; the stools are said to be normal (subsequent observation *showed excess of mucus and a large number of thread*-worms). Physical examination showed nothing abnormal. As to his family history, his father is under treatment for epilepsy. His paternal grandfather and paternal grandmother, a paternal uncle, and probably also a maternal uncle, had rheumatic fever, another maternal uncle is "weak-minded," and the mother's aunt is in a lunatic asylum. One paternal uncle is said to have had similar "terrors" in early childhood but no definite account could be obtained.

Case 3.—A girl, aged four and a half years, for the last nine months has had attacks of screaming during the day. No satisfactory details of the attacks could be obtained, the mother's account being confused and contradictory, especially as to whether the child seemed frightened or not. In one at least of these attacks (of which she has had six in the last fortnight) the child was thought to be screaming with fright, but usually no cause whatever *could be found for the* attacks. Before they begin the child seems "strange" in her manner and then suddenly begins screaming. This has happened while the child was sitting amusing herself at the piano or in the midst of a game. The whole attack sometimes lasts about 15 minutes. No hallucinations or delusions were noticed, but the mother's lack of observation made this quite uncertain. For three months at least the child has had night-terrors, apparently with visual hallucinations, and for a long time has talked much in her sleep. She is extremely excitable and rather precocious. Occasionally she complains of vague abdominal pains. Physical examination showed a musical systolic bruit at the apex of the heart, but there was no history of rheumatism. As regards her family history, the mother is said to have had severe "rheumatism."

To these three cases may be added the two cases recorded by Henoch.

Case 4.—The patient was a boy, aged *seven* years, *the son* of an actor—a nervous, anæmic, delicate child. For some months as many as from 10 to 20 attacks took place daily, but never during the night. The child would shut his eyes and stop his ears, crying, "I'm afraid," and cling to his mother. The duration of the attack was only a few seconds. The child was otherwise healthy and, in particular, was free from other hysterical symptoms.

Case 5.—A "nervous" child, aged six years, had suffered from pavor nocturnus for seven months, with intervals of about a fortnight, and the attacks with hallucinations occurred occasionally by day. Unfortunately, both these cases were lost sight of.

The cases recorded as instances of day-terrors by Dr. Guthrie[2] in his very interesting article on Night-Terrors differ considerably from those mentioned above. In one case a girl of nine years of age was said to have "*gone out of her mind* during the night." At the middle of the following day she was still sitting in bed flushed and wide eyed and was screaming madly of "black dogs" and "men under the bed." She was removed to the hospital and a few hours later she recovered her senses. In the other case a boy, aged eight years, with hectic temperature due to spinal caries and abscess, awoke at 9.30 P.M. screaming, "Robbers! murderers!" and continued in a maniacal condition with various delusions for three whole days. In these two cases the condition is not the transitory paroxysm to which Henoch alluded as "pavor diurnus or day-terrors," but a much more permanent condition, lasting many hours, or even days, with no intermission, and it may be doubted whether it would not be better to include such cases under the head of mania rather than under that of day terrors The distinction is a fine one and perhaps only a verbal one for it occasionally happens that night terrors last fully half an hour with almost maniacal symptoms and it is quite conceivable that day terrors may run a similar course, but even so a paroxysm which usually lasts a few seconds or minutes and is occasionally prolonged to half an hour falls into a somewhat different category from a continuous state lasting from one to three days, such as Dr Guthrie describes The name "day terrors' seems more appropriate for such cases as Henoch has described—transient paroxysms of terror, closely resembling night terrors except that they occur in the waking condition

---

[1] Lectures on Children's Diseases, Translations of the New Sydenham Society, 1889, vol. i., p. 241.

[2] On Night-Terrors, Allbutt's System of Medicine, vol. viii., p. 228

The relation of these attacks to night-terrors seems to require some definition It is evident that the relation is very close, in four cases out of the five night terrors were or had been present, and it would seem that the day attacks may be associated with them or replace them But the difference between the night and the day attacks is not merely one of time of occurrence, there is the far more important difference that while the characteristic of the night terror is its onset during sleep the characteristic of the day terror is its occurrence in the waking condition It has happened that a child has fallen asleep in the daytime and then has had an attack exactly similar to night terrors but such an attack, although it occurred in the daytime is not a day terror Conversely, there is reason to believe that a "day terror" may occur at night In Case 1 the mother, a very intelligent observer, was familiar with the character of night terrors from the attacks which the boy had experienced some months earlier, and she particularly noticed that the supposed "night-terrors' at the later date differed from the previous ones in that the boy was wide awake when the attacks occurred I would suggest therefore, that it would be very much better to distinguish these conditions as ' sleep-terrors ' and "waking terrors '

The symptoms of waking terrors or day terrors are fairly constant A nervous, excitable child, in the midst of his play or while sitting quietly in a room with other people suddenly without any apparent cause begins to scream and looks terrified Sometimes he says that some imaginary person is coming after him or that he hears something which frightens him or he has some other form of hallucination or delusion He rushes screaming to his mother or to some other person for protection and no coaxing or attempts to soothe seem to have any effect in pacifying him In one case when the attacks occurred the child had a strange look about the eyes which the father described as "a vacant look This child also turned pale, as children very readily do with fear There was never any loss of consciousness in any of the cases and in all of them the children recognised those about them It must be mentioned however, that Dr J F. Goodhart states that in these attacks the child sometimes shows a definite dread of a nurse or of the mother, of whom in times of health the child is even inordinately fond and he also says he has known a child to be quite maniacal in the attacks The duration of the attacks varied from a few seconds up to about a quarter of an hour and their frequency varied from one in a fortnight up to 20 in a day It is important to notice that although the day attacks may be associated with night-terrors they may also occur without any nocturnal symptoms

The etiology of day terrors is as difficult to determine as that of night-terrors One thing seems clear that the children who suffer from day terrors are children of excitable nervous temperament The family history of rheumatism in all the three cases under my care seems to point in the same direction In seeing a large number of children one is struck with the sensitive nervous temperament of those who come from rheumatic families No small number of such children show one or other of the minor functional neuroses, it may be some habit spasm or nocturnal enuresis or it may be recurring headaches or ' nervous diarrhœa,' or it may be simply undue excitability The family history of rheumatism, therefore is probably more than a mere accident, and it is interesting to note that in night-terrors Dr Goodhart[3] found a family history of rheumatism in 19 out of 37 cases, and Dr Graham Little[4] found valvular murmurs in the heart in 17 out of 30 cases In Case 2 the neurotic inheritance was even more marked, for as stated above the father was epileptic, one uncle was 'weak minded,' and the mother's aunt was in a lunatic asylum

The determination of the exciting cause of these attacks involves some consideration of their nature As I have already mentioned there is no apparent objective cause, but it must be noticed that some of these children are exceedingly timid even in the intervals between the attacks In Case 1 the noise of the fall of an umbrella stand caused quite disproportionate terror, and Case 2 was terrified by the smoke of a train It might therefore be suggested that sometimes at least an objective cause is present which may be so slight as to be overlooked by the parents, but is magnified by a fanciful child into something terrific Such a possibility is difficult to exclude but in the cases recorded above the attacks seemed in almost every instance to be entirely independent of any objective cause

The question then arises whether these attacks are identical in their nature with night terrors The wide difference in the conditions under which they occur—viz, during sleep in the one case and in the active waking condition in the other—makes this a question of considerable interest Most writers have discussed the nature of night-terrors on the assumption that sleep was a necessary factor in the production of the terror, and the distorted fancies of the sub conscious condition of sleep, with or without some reflex stimulus, have been supposed to be the terrifying agent Such a theory evidently must be modified if it is admitted that day terrors are identical in their nature with night terrors It seems difficult to doubt this identity, the repeated association of the two conditions clinically the fact that day terrors may replace night terrors or *vice versa*, and the close similarity of the attacks, which in both consist of a sudden transient terror with the presence sometimes of hallucinations or delusions —all these points make it more than probable that the two conditions are identical in their nature This being so it is not sufficient to say of night terrors that they are simply "children's night-mare bad and terrifying dreams' for exactly similar attacks occur during the daytime when the child is wide awake and busy at play, and moreover, as I have pointed out above, it seems at least probable that attacks may occur at night which are really not ' sleep-terrors' but "waking terrors'

Some writers have considered night terrors as closely allied to or even identical with, epilepsy, and the occurrence of similar attacks in the waking condition might be thought to favour this view The aura of epilepsy, as is well known, sometimes consists of a feeling of fear, moreover, those who suffer from epilepsy may in abortive attacks experience the aura only so that it might be suggested that in day terrors we have an epileptic condition in which only the psychical symptoms corresponding to the aura of the major attack are present There are however, I think, some points which are opposed to this view So far as the very scanty experience before us is available there is as yet no evidence that these children are specially liable to ordinary attacks of *petit mal* or major epilepsy, as one might expect if these attacks were indeed a masked form of epilepsy The results of treatment moreover, in the two conditions would seem to be very different, for while epilepsy is usually difficult to cure day terrors seem to be easily cured by very simple treatment Further, although the administration of bromide produces a rapid improvement in day terrors apparently no such sedative is necessary Such treatment as an alkali to remedy the digestive disorder which is present in some cases or the removal of threadworms or of any other local irritant would seem to be sufficient These points, however, require the confirmation of further experience Although, however day terrors are probably not to be regarded as masked epilepsy it seems certain that they are to this extent allied to epilepsy that they are a form of paroxysmal neurosis, and as such no doubt fall into the same group of functional disturbances as migraine and *petit mal* At the same time there is obviously only a narrow line between day terrors and some forms of insanity, and perhaps one may sum up one's impression of pavor diurnus by saying that it is a paroxysmal psycho neurosis allied to, but not identical with epilepsy on the one hand and hysteria and insanity on the other

From what has been said above it will be seen that whatever view may be adopted of the nature of day terrors the same must also be adopted for night terrors and it is easy to imagine that just as the motor cortex is liable to be affected by a paroxysmal neurosis—viz, epilepsy—at night (and in some cases only at night), so also the higher centres may be specially liable to paroxysmal disturbance during sleep. The far greater prevalence of night-terrors than of day-terrors may well be related to the extraordinary sensitiveness and activity of some of the higher centres during sleep, which is seen in the readiness with which a stimulus which in the waking condition would produce little or no effect will during sleep start a whole series of reactions (dreams as we call them) in the higher centres. While, however, it seems most probable that both night-terrors and day-terrors should be regarded as paroxysmal neuroses, the attacks during sleep are in my experience *rarely, if ever*, idiopathic. Almost always an exciting cause can be found and its causal relation proved by the cessation of the attacks after its removal; and I should suspect, therefore, that day-terrors also will prove to be symptomatic rather than idiopathic. In the case of night-terrors my own experience has been that in the vast majority the exciting cause is some gastro-intestinal disorder, and by far the most common cause is that chronic catarrhal condition to which Dr. Eustace Smith gave the name of "mucous disease." The insidious character of this disorder may account for the discrepancy of opinion as to the part played by gastro-intestinal disorders in night-terrors. It is not the glaring case of diarrhœa or the troublesome case of vomiting that is to be looked for with night-terrors, but a much less obvious condition which has often not attracted the mother's attention at all. The children are "peaky" and thin, often languid and irritable, the face is pale or sallow with a bluish translucent puffiness of the lower eyelids, the appetite is capricious, the bowels are costive rather than loose, and the stools contain—not necessarily continuously but from time to time—an excess of mucus, or "slime" as the mother calls it. Sometimes there is some vague complaint of occasional abdominal discomfort and often threadworms are present. These are the symptoms which one finds so often with night-terrors, and whatever they may mean—and it seems probable enough that they indicate a chronic catarrh of the large intestine—their causal relation to night-terrors is made almost certain by the disappearance of the night-terrors when the gastro-intestinal disorder is cured. I have alluded to this point in some detail because it seems that day-terrors may be excited by this same reflex stimulus from the gastro-intestinal tract. In two of the three cases under my care this chronic catarrhal condition of the bowel was thought to be present and in both cases the good effect of potassium citrate, together with rigid dieting, was very marked. In Case 2 after a few weeks the child passed a large number of threadworms one day, and although the day-terrors had much diminished before this, both they and the night-terrors seem to have ceased since. The effect of constipation was marked in this case; it was particularly observed that the day-terrors were more frequent when the bowels were confined. In Case 3 the mother volunteered the information that the child complained frequently of stomach-ache, but apparently *not at the time* of the attacks. It *seems*, therefore, that the exciting cause of day-terrors is, in some cases at least, some gastro-intestinal disorder, but that the attacks are not due to any painful sensation. Some observers have thought that night-terrors are produced by respiratory difficulty, particularly by the obstruction caused by adenoids. So far as my own experience goes this is quite exceptional and there was nothing to suggest any such cause in the three cases mentioned above. At the same time it seems quite likely that if such peripheral irritation as the chronic disorder of the bowel mentioned above may be the exciting cause of day-terrors, other forms of irritation, such as interference with respiration by adenoids, might also cause them.

---

[3] Diseases of Children, sixth edition, p. 531.

[4] Brit Med Jour August 19th 1899

The immediate prognosis in day-terrors would seem to be good. They are easily diminished by treatment and probably the cure is permanent so long as the exciting cause, whatever it may be, is avoided. There is no experience at hand, however, to determine what the future of these children may be. It is an approved fact that epilepsy does occasionally occur in later years when night-terrors have occurred in childhood; and in such a case as the second, where there was a family history of neuroses, including epilepsy, the occurrence of day-terrors must cause some anxiety. The significance of day-terrors as a danger signal of tendencies to more serious neuroses in later life is probably graver than that of night-terrors, for the occurrence of day-terrors no doubt means that the nervous instability which favours night-terrors is present in larger degree.

The most important part of treatment is the cure of the exciting cause. The chronic intestinal catarrh mentioned above calls for rigid dieting, particularly the exclusion of potatoes, pastry, and sugar, and at the same time the administration of an alkali. Potassium citrate is the drug I have found most useful, and this may be given with iron and compound decoction of aloes as recommended by Dr. Eustace Smith. Threadworms or other causes of irritation must be removed by suitable treatment. The intestinal disorders are not likely to be cured off-hand, and it may be desirable therefore to use sedatives as well. The good effect of bromides is almost immediate, and given in combination with belladonna they produce a very rapid diminution in the number and intensity of the attacks. Lastly, if night-terrors are, as Dr. Goodhart puts it, the "slacken-speed" to the engine-driver, then *a fortiori* I think day-terrors must be regarded as an indication for the utmost caution in the matter both of school and of play. A child who has had day-terrors is not the child to be goaded up to the inspector's standard, nor is it to be made the show-child of a kindergarten. In school and in play the child must be kept as far as possible from all excitement and mental strain. The cruelty and baneful effects of frightening such children, whether in punishment or in jest, hardly need to be mentioned here.

Gower-street, W.C.

SOME REFLECTIONS UPON APPENDICITIS.

BY J. O'CONOR, M.A., M.D. T.C.D.,
SENIOR MEDICAL OFFICER, BRITISH HOSPITAL, BUENOS AYRES.

NOTWITHSTANDING the results universally obtained by the timely adoption of surgical measures in appendicitis many still maintain that a large percentage of recoveries follows medicinal or expectant treatment and that surgery is, to say the least, superfluous in those cases which they designate catarrhal or simple appendicitis. Also opinions are by no means in unison as to the etiology of this complaint; some claim the universal provider, uric acid; some attribute it to the irascibility of the bacillus coli; *others* give mechanical reasons; while not a few, including the writer, consider it to be of mixed origin. I should like to suggest for the consideration of bacteriologists the possibility of the germ (or a congener) of acute infective arthritis (rheumatic fever), which seems to have a partiality for waging war *viâ* the lymphoid tissue, taking a prominent part in the attack.

The general practitioner may well say, "For modes of faith let graceless zealots fight," but what am I to do or think when called on to treat a case of appendicitis? He may console himself with the idea that the majority of observers agree that the disease is primarily a local one, probably caused by some mechanical irritation which lessens the vitality of the tissues and thus renders them an easy prey to infective microbes, and that this apparently functionless organ is particularly prone to infection, congestion, ulceration, and gangrene on account of its peculiar anatomical formation, limited blood-supply, and trap-door situation. As to treatment, it may with advantage be remembered that "the heresy of one generation is the creed of the next." It appears somewhat paradoxical that pathology cannot be reckoned on to give much assistance in simplifying matters, for many medical men of high repute refuse to admit the justification, much less the necessity, of examining the affected organ except by touch through the thick layers of the abdominal muscles, and to a great extent they draw their pathological inferences from general clinical manifestations, while others hold that inspection of the lesion is a *sine quâ non* in arriving at a correct conclusion. Considering the ubiquitous prevalence of the malady and the thousands of operations which have been successfully performed for its relief, surely such confliction of ideas is not consistent with the advanced state of our science.

From a personal experience of 72 consecutive operations for appendicitis I have learned not to place much value on ante-operative classifications, such as catarrhal, suppurative, and gangrenous, for I have frequently observed that such fine-drawn distinctions are illusory; to say the most they only imply mere transition stages of the same disease, which cannot be differentiated with certainty without abdominal exploration. I should think there are few surgeons who if called into consultation in a case of appendicitis, and finding the patient with a drum abdomen, rapid pulse and vomiting, would not sum up the condition as perforation with diffuse infective peritonitis, or if they met with a tense, painful, circumscribed swelling in the cæcal region would not diagnose appendical abscess. Place aside these two obvious and late phases of the affection I venture to ask, Is there a physician or surgeon to be found who can define the pathological condition sufficiently correctly on which to base scientifically an expectant plan of treatment? Is it possible to exclude a rapidly thinning stricture? Can early abscess formation between adjacent coils of bowel be eliminated? Can it be positively stated that the appendix is only congested, not distended with feculent pus, or that it is not rapidly becoming gangrenous, that there is not some foreign body or infective concretion on the verge of *bursting into the abdominal cavity and can the formation of* protective adhesions be divined? I make bold to assert emphatically that these questions can only be answered by the introduction of the sense of sight and that clinical inferences are often miserable delusions in this disease. Imagine the feelings of an educated medical man on finding the patient whom he left at night with a flat abdomen and in a good general condition on his arrival the next morning with a blown out abdomen and all the symptoms of peritonism—no retreat but the grave. Is this a fanciful picture? I challenge anyone who has had any experience worth mentioning in appendicitis to deny the insidious rapidity with which a "simple" case may become converted into a fatal one.

Some may ask, Why operate in every case when a large percentage undergo spontaneous cure? My reply is (1) I cannot say at the onset of any case that spontaneous cure will take place, (2) I am unable to guarantee that perforation without previous formation of protective adhesions may not suddenly occur, which complication in my experience is invariably fatal, (3) cœliotomy with removal of the appendix is the most accurate method of diagnosis and cure with which I am acquainted, the operator is to be congratulated for his promptitude if he only encounters the catarrhal variety and moreover, the patient is com*forted with the assurance that the operation*, proved to be a simple one and devoid of risk, ensures that he will never again suffer from appendicitis, and (4) I am sceptical as to large numbers of expectant "cures." An appendix once infected is always infected and remains a weak spot, and although in some cases no actual recurrence takes place yet in a great many permanent adhesions have formed around the appendix and the cæcum which cause chronic digestive disturbance with or without dragging pain and tenderness in the right iliac fossa. The appendix during an attack frequently becomes glued to adjoining structures. On two occasions I found it adherent to the right ovary and in each instance it caused chronic ovarian irritation. Occasionally I found it adherent to the pelvic floor, tying down the cæcum in a tent rope fashion. In such cases pain, tenderness, and flatulence had been complained of for a long period. Removal of the adhesions and the tent rope appendix effected a permanent cure.

Another condition which deserves mention is the influence of an abnormally short *meso-appendix* on the movement and shape of the appendix. On four occasions I operated purposely to relieve chronic indigestion, with pain and tenderness at McBurney's point, and found that the appendix was bound down below the cæcum by a stunted meso appendix with kinking, at the point of the distal attachment of the mesentery. In each instance it was impossible to raise the appendix to the surface until the meso appendix was divided, whereupon it could with facility be lifted out of the wound. It is not hard to realise that each time the cæcum became distended with fæces and gas a kind of tent rope action came into play and caused the above symptoms. I cannot imagine a more dangerous condition in case of the supervention of an attack of appendicitis for it is obvious that stricture and perforation would rapidly take place at the site of kinking. I may mention that the four patients were cured of their chronic trouble by removal of the appendix.

The following case affords a good illustration of such a danger. A few months ago I had the pleasure of being assisted in an operation for appendicitis by Dr Barry of H.M.S. *Pegasus*. We found the appendix bound down behind the cæcum by a stunted meso-appendix and at the point of the distal attachment of the latter there was marked angulation. The distal end of the appendix was intensely inflamed and contained a concretion of about the size of a pea, while the proximal portion appeared to be perfectly normal. After removal it was found that there was a stricture at the site of the kink, with ulceration extending through all the coats excepting the serous one; and as no external adhesions were forming it may be reasonably inferred that the operation not only cured the appendicitis but saved the patient's life. He would indeed have been a far seeing clinician who could have inferred the pathological lesion of this most interesting case.

It would be superfluous for me to mention anything about the danger of intestinal bands forming after inflammation in this region further than to refer anyone interested in this matter to Mr Treves's most excellent work on "Intestinal Obstruction." Another proof of the difficulties which attend *diagnosis came under my observation on Nov 5th, 1899*. A strong young man was suddenly seized with severe pain in the umbilical region on Oct 26th. He vomited frequently during the next three days and complained of fever and constipation, with pain and tenderness in the right lower abdomen. The first medical man in attendance was said to have diagnosed gastric influenza and administered a purge which acted freely, nothing abnormal was found in the stools. A second medical man was reported to have said that it was inflammation of the liver and advised his removal to Buenos Ayres, which meant a long drive and a train journey of 350 miles. On admission to hospital on Nov 5th his temperature was 100° F, the pulse was 80, the tongue was furred, and his gait was "down on the right." He volunteered the statement "that he felt better"—in fact he thought "the trip did him good." Abdominal examination showed that there was no distension or limitation of normal respiratory movement and no redness or localised tumefaction. He complained of slight pain in the right inguinal and umbilical regions with slight tenderness on palpation, *not* particularly marked at McBurney's point. No tumour could be detected, but there was a distinct board like feeling of the right oblique muscles, and movement of the right lower limb caused him some pain. On Nov 6th the morning temperature was 99°, the bowels responded readily to a soap-and water enema, the tongue was cleaning, muscular resistance was diminished, and the pulse was 76. In the evening the temperature was 99 6°. On Nov 7th the morning temperature was 98 2°. There was no further development in the abdominal symptoms and he felt "almost well." Diagnosis, con*valescence from appendicitis*. *Considering the out of the* way place in which the patient resided I advised the removal of the appendix as a matter of future safety, to which he consented. The evening temperature was 98 6°; the bowels again acted with an enema. On Nov 8th the temperature and pulse were normal and the patient felt "quite well." Chloroform was administered and on deep palpation a hard tubular form of swelling was found in the cæcal region extending upwards along the line of the ascending colon. Cœliotomy was then performed, the cæcum presented a normal appearance, but on searching for the appendix the cæcum and the ascending colon were found to be densely adherent on their posterior surfaces to a hard mass deeply situated in the right iliac fossa. The adhesions were being gently separated from the outer side when a sudden gush of fœtid green pus (about four ounces in all) took place which came from a long narrow abscess cavity situated directly behind the cæcum and the ascending colon and extending from the brim of the pelvis almost *to the lower border of the liver*. *The pus was sponged* out and the pyogenic cavity was laid open in its entire length. After a prolonged and difficult search the appendix was found to be disorganised and firmly adherent to the posterior surface of the cæcum, with a small perforation at its junction with the latter. (The absence of marked tenderness at McBurney's point I presume was due to the position of the appendix.) The appendix was cut off flush with the cæcum in order to embrace the perforation and the wound in the bowel was closed by a layer of sutures. A large drainage tube was placed alongside the cæcal wound and the usual dry dressing was applied. Three days later a fæcal fistula occurred and an abundant discharge of fæces continued for a week and then spontaneously ceased. An uninterrupted recovery followed. I do not take the least credit for the successful result for I failed to recognise the true nature of the condition until chloroform was administered for quite a different purpose—viz., to remove the possibility of recurrence.

cases there have been four deaths—three due to ante-operative perforation with diffuse infective peritonitis and one to pyophlebitis in a suppurative case of one month's duration before admission to hospital. In 26 cases there was suppuration with localised peritonitis, which in some instances had invaded by direct contiguity two or three coils of adjacent bowel. Needless to state, no selective process was adopted in this series and the death-rate—5 5 per cent.—may not compare unfavourably with other methods of treatment.

It has been my practice for some few years past to operate as soon as possible after diagnosing the complaint. The local skin disinfection having been gently carried out McBurney's cœliotomy is performed, and if any tumefaction is felt the incision is made directly over it. I cannot see any necessity for semilunar or median incisions, for in the majority of cases by careful sponge packing the general peritoneal cavity can be more easily shut off through the oblique incision. Some time ago Sir William Banks called attention to the value of attacking an appendical abscess extra-peritoneally, and my experience tends in every way to confirm the teaching of that distinguished surgeon.

Many surgeons still advocate leaving behind the appendix when obscured by adhesions in the face of pus. In this I cannot agree, for I know of four cases where suppuration recurred, eventually necessitating removal of the organ. I make it a rule never to quit the abdomen when operating for appendicitis without removing the appendix, and on three occasions I proved the value of my resolve, for I discovered a second collection of pus when searching for the appendix which undoubtedly would have been otherwise overlooked. I have over and over again broken down intestinal adhesions and have never yet caused fresh infection, which I attribute to the fact that I strive to let the light into a pus collection and clean up before proceeding further.

The key of the situation is, without doubt, *patience*. It is surprising what changes can be wrought in a foul appendical abscess cavity by five minutes' gentle sponging and a pair of good retractors. The trouble and time taken are amply rewarded when the *fons et origo mali* is brought into view nd removed. Leaving a moribund appendix in a living abdomen is not sound surgery.

Buenos Ayres

FURTHER OBSERVATIONS ON PERNICIOUS ANÆMIA (SEVEN CASES): A CHRONIC INFECTIVE DISEASE;

ITS RELATION TO INFECTION FROM THE MOUTH AND STOMACH; SUGGESTED SERUM TREATMENT.

BY WILLIAM HUNTER, M.D.EDIN., F.R.C.P.LOND.,
PHYSICIAN TO ELECTRICAL DEPARTMENT, JOINT LECTURER ON PRACTICAL MEDICINE, AND PATHOLOGIST, CHARING CROSS HOSPITAL, SENIOR ASSISTANT PHYSICIAN TO THE LONDON FEVER HOSPITAL.

(*Continued from page 224.*)

THE first part of this paper will serve to explain the origin and development of my interest in the mouth in connexion with pernicious anæmia. In all of the cases, it will be seen, there was found some morbid condition sufficient by its character or its intensity to attract the special attention of either the patient or myself. The actual conditions met with were:—1. Marked cario-necrosis of the teeth, antecedent or existing, in all cases. 2. Conditions of glossitis or stomatitis, characterised by great tenderness, presence of sores, and salivation (in four cases): (*a*) In no fewer than four cases the condition of the mouth formed one of the chief subjects of complaint on the part of the patient (Cases 1, 2, 4, and 8). (*b*) In all of the four cases the morbid condition of the mouth seemed to be connected with the origin of the disease, either preceding the weakness (Cases 1, 2, and 8) or being most troublesome in the early stage of the disease (Case 4). In other words, the condition was not simply the result of weakness; on the contrary it was most marked at the commencement where the anæmia was slight, and in each case became less marked as the anæmia increased. (*c*) In two cases (Cases 2 and 8) the patients themselves in their own minds connected the onset of their weakness in some mysterious way with the stomatitis As one of the patients strikingly put it, "the trouble of the mouth seemed to go right through him." 3. In all cases there was evidence of gastric or intestinal trouble, or both—discomfort, sickness, retching, vomiting, diarrhœa—and in two cases (in which were present morbid conditions of the mouth, dental caries, glossitis, or stomatitis) there was gastritis (Case 1) and infective gastric catarrh (Case 8). 4. Lastly, the possibility of any connexion between the dental and oral condition and the gastric condition was elucidated by the case (Case 7) in which I was able to demonstrate in the most striking manner the origin of infective gastric catarrh from infection with the organisms of dental necrosis.

IV.—DENTAL DISEASE AS A CAUSE OF INFECTIVE GASTRITIS.

Case 7 I regard as specially interesting. It demonstrates to my mind a relationship between cario necrosis of the teeth and gastric catarrh, of a closer and more direct character than I had hitherto recognised, or, so far as I know, had been recognised by others. That relationship I may thus describe: that there is a limit to the capacity even of the stomach to resist indefinitely for periods of years the continuous presence of pyogenic (pus-forming) and other organisms in its contents derived from cario-necrotic conditions of the teeth; that its powers of destroying such organisms, although great, are never complete even in health; that these powers become progressively weakened when through any cause an increased and continuous supply of infective organisms is associated with a diminished and continually lessening acidity of the gastric juice; that these two conditions are precisely those produced by chronic cario-necrosis of the teeth; and that in time the catarrh of the stomach, so common a sequel of imperfect dentition—possibly of simply irritant nature to begin with—may in time become infective in its character, leading in time to the deeper-seated changes which always result from chronic catarrh—viz., atrophy of secreting structures, with increase of fibrous tissue (chronic gastritis with atrophy of the glands).

These statements as to the relation between dental cario-necrosis and gastric catarrh I have elucidated and supported elsewhere;[1] but some brief reference to the subject is here necessary to a right understanding of our present subject—to wit, the meaning and significance of the dental and oral conditions met with in pernicious anæmia.

The relation between dental disease and ill-health.—That health is to a large degree conditioned by the state of the teeth—their presence or absence, their soundness, their freedom from pain—is generally recognised; but if inquiry were made as to the nature of the connexion opinions would be found to differ. 1. In the minds of most, probably, the relation is what one may term a "mechanical" one. Carious teeth mean imperfect mastication, consequent increased and unnecessary work for the stomach, this leading in course of time to the various ills and worries connected with impaired digestion. Such a mechanical relation is by no means the only or the most important relation of dental disease to general health. 2 In the minds of others the connexion between bad teeth and bad health is supposed to be of another kind—viz., that bad teeth denote bad nutrition and bad health. They are the result of ill-health rather than the cause of it. 3. A third possible relationship—one that appears to me to be altogether insufficiently recognised, still very obscure, but in my opinion even more important than either of the two above mentioned—is dental disease as a cause of ill-health in consequence of being a continual source of septic poisoning and septic infection, both local and general.

Local infections —Among the obvious conditions of this nature are the various local inflammatory and suppurative conditions met with in the mouth (periostitis, alveolar abscess, suppuration around decayed teeth, and pyorrhœa alveolaris); or in the jaws (periostitis, osteitis, osteomyelitis, necrosis, and suppuration in maxillary sinuses), or in tissues adjacent to the mouth (inflammation and suppuration of the glands of the neck, cellulitis of the neck, post-pharyngeal abscess, thrombosis of the vein, and even meningitis by direct extension).

Remote infections —Among the remote conditions of infective nature the origin of which is still obscure and which may in certain cases be traceable back to infection from the mouth are such *conditions as acute osteomyelitis*, acute necrosis occurring apart from injury, suppurative meningitis, empyema, ulcerative endocarditis, and acute nephritis. The *special interest of dental disease in connexion* with this class of cases arises from this: that dental cario-necrosis is the commonest and most prevalent infection in the *body*; and *that this infection is of a "mixed" character*, including not only harmless organisms, but also the most active pathogenic blood-poisoning organisms—viz., streptococci and staphylococci.

---

[1] Relations of Dental Disease to General Diseases and to Infective Gastritis, Transactions of the Odontological Society of Great Britain, Feb. 6th, 1899.

Bacteriology of dental caries.—On this point—the infective nature of dental caries—I need not dwell. The evidence so abundantly furnished by the laborious bacteriological observations of Miller (1884-1894) on no fewer than 250 cases of diseased teeth, of Galippe and Vignal (1889), of Jung (1893), and most recently of Professor Arkovy of Budapest (1878-1898) seems to me conclusive. With the minutest bacteriological precautions, which I have detailed elsewhere,[2] the last-mentioned observer has in 43 cases studied in detail the organisms found in the most various conditions of teeth—e.g., gangrene of pulp (both acute and chronic), chronic alveolar abscess, old stoppings, &c. The chief result of the observations from the dental point of view is to show that one organism is constantly to be found in diseased pulps and in dental caries (the bacillus gangrænæ pulpæ), possessing the power single-handed of producing gangrene of pulp and of effecting softening of a tooth *even in an alkaline medium*. Its frequency as compared with other organisms was 95·3 per cent. Next most frequent and from my present point of view even more important, were various forms of pus-organisms—viz., staphylococcus pyogenes aureus, 34·8 per cent. of cases; streptococcus pyogenes, 23·2 per cent.; staphylococcus pyogenes albus, 18·6 per cent.; bacillus pyocyaneus, 9·3 per cent.; and staphylococcus pyogenes citreus, 4·6 per cent., with nine other organisms, mostly harmless, in varying frequency. The pyogenic organisms were always absent in teeth successfully dealt with antiseptically.

The *significance attaching to these observations* in the present relation is not the mere presence of such organisms in connexion with dental caries. Their mere presence in the mouth *does not constitute* disease of the *mouth or elucidate* the pathology of stomatitis, any more than the almost constant presence of the pneumococcus in the mouth constitutes pneumonia or elucidates its pathology. Infective disease in the mouth as elsewhere is not, fortunately, a mere question of the presence of an organism, however pathogenic, but a question of *dose* and *resistance*. And in the case of the mouth the question of dose becomes a very important one when we have to deal, not with an isolated carious tooth but with a whole series, sometimes a whole mouthful, of such teeth, not only dark and necrotic themselves, but lying in inflamed, possibly (as in Case 7) actively suppurating, sockets. The effects of such a condition I consider to be twofold: one a general and the other a more local effect. The general effect is a septic absorption from the diseased teeth and sockets, which, continued as it often is over many years, must in the aggregate be of remarkable extent. The local effects are primarily on the mouth itself, and are sufficiently obvious in the oral *sepsis so common in such cases*; secondarily on the stomach. The continous swallowing of mouthfuls of pus organisms is not tolerated indefinitely by the stomach mucosa. The number of organisms that enter the *stomach* from the mouth is very large, the most of them to be destroyed, fortunately, by the gastric juice. But this is by no means true of all. A very considerable proportion (as many as eight out of 25 according to Professor Miller) are to be found in the stomach contents. The observations of Macfadyen and others show that only a certain proportion are destroyed by the gastric juice. It is only when the acidity of the gastric juice is considerable—e.g., an hour or two after food—that it exercises any direct bactericidal action.

In long-standing dental disease the conditions are thus precisely those most likely to produce infection of the *stomach*—viz., on *the one* hand, *diminished* resistance, i.e., diminished acidity as a result of the chronic indigestion and catarrh, and, on the other hand, increase of dose, i.e., increased supply of pus organisms from the necrotic teeth. That under such circumstances disturbances may arise, and

the stomach is a fact to which both clinical and pathological *experience testifies*, and one, too, that is generally recognised. What, however, Case 7 demonstrates is that the effect is not limited to a mere fermentation of food products, but that *actual infection of the mucosa* with pathogenic organisms may itself occur. The mucosa of the stomach continuously exposed to infection—e.g., of pus organisms from *the teeth—becomes eventually infected*. An infective catarrh is set up and sustained by continuous influx of organisms into the stomach, and if continued long enough this chronic catarrh leads *to the usual effects of a glandular catarrh*—viz., glandular atrophy with increase of interstitial tissue around.

These considerations as to the possible effects, both general and local, of long-continued dental and oral sepsis are of no mere theoretical interest. On the contrary, they are, to my mind, of supreme practical importance, exemplified as they are (to a degree which I consider altogether insufficiently recognised) in almost daily experience by the cases one meets with of gastric catarrh in association with dental decay. The ashy-grey look and general languor which such patients, in my experience, characteristically present I regard as manifestations of long-continued septic absorption; while the local symptoms of clamminess of the mouth, distaste for food, coated tongue, and indigestion, which one simply looks upon as manifestations of gastric catarrh, may really be, as in the case which I have described (Case 7), the result of infective gastric catarrh produced by direct infection of the stomach with the pus organisms. Case 7 appears to me to present points of unique interest in demonstrating the actual relations between dental infection and gastritis—viz., the history of nausea and vomiting; gastric pain extending over a period of months; the pain so severe as to necessitate the use of opium and suggesting cancer; the scrupulous cleanliness of tooth-plates and the healthiness of the gums; the absence of all teeth except three carious ones, these latter discharging pus from their roots; the removal of these three; the immediate improvement, *temporary* in character; the recurrence of sickness and vomiting; the vomit three weeks after removal of the teeth still loaded with pus organisms; the *administration of salicylic acid as a local antiseptic*; the entire cessation of all gastric symptoms in three days; in three months a gain of a stone in weight; and, lastly, the permanency of the cure. Fifteen months later the patient wrote that she had never had any return of the sickness.

V.—THE RELATION OF DENTAL CARIES AND STOMATITIS TO PERNICIOUS ANÆMIA.

I have been careful in the foregoing section to define as clearly as possible what I consider to be the relation which frequently exists between *dental-cario-necrosis* on the one hand and gastric catarrh with general ill-health on the other. I have done so by way of clearing the ground for what now *remains to be considered*—viz., *the significance* to be attached to the oral conditions met with in the foregoing cases of pernicious anæmia and their relation to the anæmia. The first statement which I have to make is that *to the various* morbid conditions of the alimentary canal occasionally met with in cases of pernicious anæmia must be added certain morbid conditions of the mouth—viz., dental cario-necrosis, glossitis, and stomatitis. The other morbid conditions include—(1) atrophy of the mucous membrane of the stomach or of the gastric glands and chronic gastritis (Fenwick, Nothnagel, Nolen, and Hunter); (2) ulcers of the stomach and duodenum (Zahn); (3) duodenitis (Homollo); (4) chronic fibrotic changes, with more recent hyperæmia and necrosis of colon (Morley Fletcher[3]); (5) cicatrices of healed ulcers and a little diphtheritic exudation in the larger intestine (Hale White[4]); (6) degenerative changes in the abdominal sympathetic ganglia (*Banti*) or *in the nerves and* ganglia of the intestinal walls (Sasaki); (7) the presence of intestinal worms (Baumber, Reyher, Rimeberg, Sahli); and (8) cancer of the stomach.

In estimating the significance of these conditions in relation to pernicious anæmia, the standard of criticism I used was, that only in isolated cases had such changes been found; and that similar changes, sometimes even more marked, were constantly met with without any of the features of pernicious anæmia. As the causes of the anæmia sometimes found associated with them I could not now described I have to apply the same standard, and with a like result. Dental cario-necrosis is far too common to be itself the cause of so rare a disease as pernicious anæmia. Stomatitis and glossitis although not so common are also too common to be the direct cause of so rare a disease; as the essential anatomical condition underlying the disease, even in the cases in which they are present, they cannot therefore, in my opinion, be regarded. Nevertheless, while they cannot be regarded as causes of the disease, they have, I consider, a very special significance, especially the conditions met with in the tongue. Their mode of onset, their character, and their progress, all denote, I consider, their infective nature, *and the special significance attaching to them in my mind is that their existence points to an infection of a definite character localised to the alimentary tract.*

Special Features of the Stomatitis.

Mode of onset.—The origin of the stomatitis was in all cases as mysterious, sometimes as sudden, as the weakness itself. The conditions were not simply the result of the anæmia. On the contrary, when they were of a character (by discomfort or painfulness) to attract the attention of the patient, they were always noticed at the onset of the disease or early in its course, and in most cases they actually subsided as the anæmia progressed. So closely connected were they, indeed, with the origin of the disease that in three cases they were among the first symptoms noticed and complained of, and in three cases the patients dated their weakness from the onset of the trouble in the mouth, one patient of his own accord describing his illness "as if the trouble in his mouth had gone right through him."

Definite character of the infection.—In the first case I observed, I was struck by the curious character of the sores on the tongue—localised inflamed patches sometimes showing vesicles filled with clear serum situated under the tip of the tongue, the inflamed areas shifting from time to time, with atrophic appearance of the intervening mucosa. The condition thus described is not one of ordinary stomatitis or glossitis such as one meets with as the result of the local irritation of decayed or irregular teeth. And this appears to hold true for the other cases described, as much from the intensity and character of the glossitis as from the situation of the sores. Thus in Case 1 the terms used to describe the condition of tongue are "tongue extremely raw and tender," "presenting a red and fiery appearance," "tenderness on swallowing extending down the throat to the stomach," likened by the patient to that of "swallowing fire." Nine months later the description was: "Whole tongue tender. On dorsum and along edges patches of more fiery redness, some under the tip of tongue showing small inflamed vesicles free of serum." Compare this with the description given by the patient (Case 3) of the condition of his tongue for a period of seven months of his illness: "Tongue raw and tender, looking like a piece of raw liver . ... causing great pain." Or with that given by the patient (Case 8) when illness began: "Some sort of painful sores in mouth under the tongue ...... not connected with the teeth ...... causing great discomfort," of such a character and intensity that his subsequent illness he described—"as if the trouble in his mouth had spread down into stomach and right through him." These are not, I conclude, the characters of an ordinary stomatitis. They appear to suggest an infection more deep-seated and severe.

"*Periodicity*" *of the stomatitis.*—Another feature I have had to note is what I may term the "periodicity" of the stomatitis—its variability from time to time, independently apparently of treatment, notably its greater severity at the outset of the disease, usually tending to subside or at least to give less discomfort as the disease advances. This feature was very noticeable in Case 1. Thus the illness was ushered in (in the autumn of 1886) with sore throat and diarrhœa, from which time "he continued to suffer at times from an inflammatory condition of throat and tongue, and his strength began gradually to fail." In January, 1888: "With the exception of some congestion of the throat and certain pale red spots on the tongue nothing further objective to be made out" (note by Sir T. Lauder Brunton). June, 1888: "Tongue extremely raw and flabby, fiery, and tender, inflamed patches with smooth mucosa between." March 9th, 1889: "Tongue not so raw-looking. Presents a more atrophied appearance, still inflamed vesicles full of serum, whole tongue tender, and mastication painful and difficult." March 20th: "Tongue lost its former fiery-red appearance, much paler, inflamed patches less marked, and vesicles entirely disappeared." And from this time onward till the death of the patient two months later the tongue ceased (for the first time since his illness began) to give him any trouble. It continued to present a smooth, flabby appearance, but the tenderness on eating was entirely lost—"he could take all kinds of food and even condiments without the slightest discomfort." The same "periodicity" is noticeable in Case 3. For a period of some seven months (October, 1894, to May, 1895) at the commencement of the illness the tongue was raw and tender, "like raw liver," causing great pain. When seen by me (October, 1895) the tongue showed nothing to attract my attention. So also in Case 8. When the illness began (June, 1898) there were painful sores under the tongue causing great discomfort. When seen by me in April, 1899, there was nothing noticeably wrong about the tongue, although there was constant salivation. During the latter part of the patient's illness (he died on Dec. 3rd, 1899) "salivation occurred when he had stomatitis; the latter was always a bother. The mouth was always clammy and uncomfortable."

I note this feature of the mouth condition, its periodicity, for this particular reason—that it recalls one of the most striking characters of the disease itself. There is perhaps no single feature of the disease more notable than the mysterious way in which, whether under treatment or not, it varies from period to period without known cause. Here, then, locally in the mouth and tongue, one has had occasion to note equally striking and unaccountable variations in intensity of what is obviously a local infective process—an intensity varying from a fiery-red inflamed appearance of tongue with intense tenderness lasting more or less over a period of several years—to a condition seen for a short time before death, when nothing was observable in the mouth except a slight atrophic appearance of the tongue and all kinds of food and drink could be taken without discomfort of any kind. Had I first seen the patient during these last weeks of his illness I could never have judged from the condition of his tongue that anything special had been wrong, the only sequel of the inflammation being a pale and atrophied appearance of the mucosa of the tongue.

This remarkable periodicity I desire to emphasise. For it irresistibly suggests the thought that if an infective process so severe in its character, so distressing, can affect one portion of the mucosa of the alimentary canal and yet disappear without leaving any obvious lesion—at most a slight atrophy, a similar infective lesion may affect other portions of the mucosa of the alimentary tract lower down, cause grave symptoms, and yet leave no obvious trace behind. In other words, an infection similar to that found in the tongue may well exist lower down, especially in the stomach, possibly in some cases in the intestine.

Such an infection of the stomach or intestine or both I consider to be the true pathogeny of this disease, and to be evidenced by and accountable for two of the striking features of the disease—(1) the prevalence of gastric and intestinal symptoms (vomiting and diarrhœa) during life; and (2) the frequency with which no obvious morbid lesions are discoverable after death, or when discoverable are found confined to the gastro-intestinal tract, especially to the stomach (gastritis, atrophy of glands, &c.).

Frequency of stomatitis in 200 cases.—The interest I attach to the condition of mouth which I have described is altogether apart from any question of its frequency or of its importance as a stomatitis. Nevertheless, in the light of these observations I have been interested in examining the records of cases with special reference to the conditions observed in the mouth. I have so far examined 200 cases, and I find references to stomatitis in 18 cases. These I append. Few as the references are, they are, I think, of interest in respect chiefly of the remarkable similarity of the appearances described by independent observers to those which I have above described. The fullest notes are those of Laache, who found the condition in four cases out of 11. His description of Case 3 might have been written for Case 1 of my own, in respect especially of the features which I have above described as specially noteworthy—viz., the tenderness, the excoriations, and the "smooth polished" (or, as I have said, "atrophied") appearance subsequently presented by the tongue. It is also notable as being the only one I can find where attention is drawn to a specially carious condition of the teeth. Of Laache's cases, Case 4 and Case 10 are also to me noteworthy in respect of the mode of onset In both cases the condition of the mouth was noted "at same time' as the onset of the illness Dr Bramwell's case is also noteworthy in the same connexion, there the condition of the mouth preceded the illness

I do not suppose for a moment that the smallness of the number (18 out of a total of over 200 cases) represents accurately the frequency of this morbid condition of the mouth When once noted the condition is so striking that it is looked for in other cases, and in this connexion I note that out of the total of 22 cases no fewer than 15 are reported by four observers—five by Müller, four by Laache, two by McPhedran, and four by myself Only one observer (Müller) draws special attention to the condition, and he was disposed to regard it as an effect of the blood condition Eichhorst thought that on account of the pain which it caused it might not be without significance

References to stomatitis —(The italics are mine)

1 Muller[5] (62 cases) Cases 20 and 23 "Stomatitis" Case 29 "Complains of very painful spots on the tongue which make eating almost impossible' Case 38 "Small ulcers in mouth which make eating almost impossible Case 39 "Stomatitis (small ulcers on the tongue and on the mucous membrane of the mouth)' Muller notes in general with regard to them ' that they were very resistant to local treatment, disappearing spontaneously or with temporary general improvement, to recur again without special cause, causing great discomfort to the patient, and great pain on eating and drinking" He thought that the stomatitis probably had some connexion with the alteration of the blood, that certain chemical products in the blood mixing with the secretion of the mouth caused irritation and ulceration in a manner similar to that described by Mosler for the parotid secretion in other diseases

2 Eichhorst[6] (91 cases) mentions the above observations of Muller, concluding that sometimes possibly on account of the pain they caused "they were not without significance I find no mention of the condition in any of his own (seven) cases except one (Case 6) where he speaks of a "bad taste in mouth

3 Laache's[7] cases (11) —Case 1 "Post mortem —On the left aryteno epiglottidean fold a round, greyish white raised spot, the size of a pea resembling an aphthous *erosion*, but showing on microscopic examination no mycelium of oidium albicans On the back wall of pharynx a slightly raised ulcerating patch the size of a bean ' Case 3 *Tongue smooth* clean, without *sign* of *papillæ* It is considerably *hacked at edges* and *painful* here Some small *excoriations* in both angles of the mouth *The teeth partly fallen out, the remainder very carious* Later "He complained not so much of weakness as of the *mouth*, which is *sensitive* and *tender* (one sees as before fissures in angles of mouth, the tongue is smooth, clean hacked at edges) He mentions he has of late lost all taste and that he had no sense of smell for several years" Two months later "*Tongue* and throat to a considerable degree *smooth* and *polished*" Case 4 The illness began with sudden onset of diarrhœa '*At same time* he became skinless' (*hautlos*) in mouth" (mouth feeling skinned) Case 8 "Tongue moist, slightly furred, no excoriations here or on lips ' Case 10 History —"In course of last winter and spring his appearance became bad, and *at the same time* he had a feeling '*of a wound*' in mouth and down the throat which prevented him taking anything but cold, fluid, and bland foods '

4 Dr Hale White[8] (29 cases). Case 14 'Complains of a coppery taste in the mouth" Case 20 "Tongue pale and flabby, partly furred, partly *raw* and *fissured* ' Case 27 'Vomiting and a *burning sensation in the mouth* with epigastric pain '

5 My own collected cases (44) Among 44 cases which I have so far analysed (from the literature of the disease between 1890 and 1894) I find the following (1) Subject to attacks of diarrhœa at short intervals and irregular vomiting The mouth sore and anus excoriated ' Arsenic always caused disturbance of stomach and bowel in a few days, "with a *metallic taste and soreness of the mouth* and increase of the anal affection.[9] (2) A child, aged two years admitted for ulceration, stomatitis, and anæmia *Exacerbations in the stomatitis*, the latter finally extending until it involved the alveolar spaces and caused the loss of two or three teeth, and finally a sequestrum three quarters of an inch long was removed from the jaw Post mortem —Stomach "*evidence of acute or chronic gastritis*"[10] (3) Often vomited *Stomatitis was troublesome* and also diarrhœa "[11] (4) Bleeding of the gums first noticed, then profuse nausea, "Tongue was clean, on left side was a deeply-drilled out *ulcer* which accounted for some of the blood which escaped The gums were spongy and bled on being touched "[12] (5) "For some time his mouth had felt very rough and dry Nausea was present[13]

6. Dr Byrom Bramwell[14] (48 cases) Case 43 (1898) Illness of several months' duration Apparent *cause* the patient herself blames mental worry A year ago she began to be troubled with sore gums (inflammation of the gums, buccal mucous membrane, and side of tongue) '

(To be concluded)

SOME

EXPERIMENTS ON THE STERILISING PROPERTIES OF UNCONFINED SUPERHEATED STEAM

BY L COBBETT, M D CANTAB, F R C S ENG,
AND
J H C DALTON, M D CANTAB
(From the Cambridge Pathological Laboratory)

As long as there remain infectious diseases the *contagium virum* of which is undiscovered the conditions necessary for the sterilisation of things suspected of being contaminated by them must remain a matter of conjecture We have to ask ourselves may we reasonably assume that these unknown germs succumb to conditions which are fatal to the most resistant of the known *pathogenic* microbes? or must we allow as a reasonable possibility that they may be still more resistant or even as much so as the hardiest micro organisms known? In other words must we aim at killing the dried spores of the hay bacillus? or may we reasonably be content with an amount of sterilising sufficient to kill the dried spores of the bacillus anthracis?

We do not attempt to answer this question, nor do we claim, though this paper deals with unconfined steam only, that it, whether saturated or superheated, is capable of destroying, within a reasonable time or in one operation, the spores of the most resistant of *non pathogenic* bacteria The object of the present paper is to report some experiments which we have made for the purpose of comparing the efficiency, for the purposes of disinfection, of current unconfined saturated steam with that of current unconfined steam which had been superheated by being passed through a series of hot pipes

I —THE PHYSICAL PROPERTIES OF SUPERHEATED STEAM

Steam or water vapour may be said to be *saturated* when no lowering of its temperature or increase of its pressure is possible without condensation The temperature at which condensation occurs varies and depends upon the quantity of steam present in a given volume—in other words, it depends upon the pressure exerted by the steam The closer together the molecules of the steam the higher is its pressure and the more readily does it condense We may therefore say that the greater is the pressure of steam the higher is its condensing point

Steam whose temperature is above its condensing point for the existing pressure is said to be *superheated* Its temperature may be lowered or its pressure raised to an extent which is proportional to the degree of superheating without condensation occurring Consequently it does not readily scald Of course, a sufficient amount of cooling or of compression will convert superheated into saturated steam

It is the property of air or other gases when mixed with steam in an unconfined space to separate its molecules and so to diminish its pressure on a given area. The pressure exerted by a mixture of gases is equal to the sum of their individual pressure. Consequently in an unconfined mixture of steam and air the pressure of the steam must be less than that of the atmosphere, for the pressure of the mixture is equal to that of the atmosphere, and some of this pressure is supported by the air. For steam to be saturated at 100° C. it is necessary that its molecules should be close enough together to exert a pressure equal to that of the atmosphere. Consequently steam at 100° C. when mixed with air at that temperature and unconfined cannot possibly be saturated; it is, in fact, superheated. It may, however, become saturated if cooled to a lower temperature or if pressure be increased so as to bring its molecules nearer together. The amount of cooling necessary to bring the steam in such a mixture to the saturation point depends upon the amount of air present. Consequently it follows that the temperature may be lowered below 100° C, and considerably so if a large proportion of air is present, without the steam, or perhaps we should now say water-vapour, becoming saturated. Superheated steam, or at least superheated vapour, therefore does not necessarily have a temperature of over 100° C.

It has been pointed out that the steam in an unconfined mixture of steam and air at 100° C. cannot possibly be saturated. It is probably for this reason that the presence of air in porous articles of clothing, &c., is so important a hindrance to sterilisation. Von Esmarch,[1] by means of experiments made with threads containing anthrax spores, found that superheated steam at atmospheric pressure was greatly inferior as a germicidal agent to saturated steam at 100° C. In the case of bulky articles, such as folded blankets, exposed to superheated steam he found that anthrax spores on the surface might remain alive even during an exposure of 30 minutes. In the interior, however, the case was different; the steam was robbed of its superheat when it penetrated into the blankets and it was then found to have the same sterilising power as saturated steam at 100°. He found that superheated steam penetrated no quicker than did saturated steam.

II.—THE HEAT GENERATED BY THE ABSORPTION OF MOISTURE BY VARIOUS ORGANIC MATERIALS.

It is, of course, well known that paper, cotton, flannel, such things have an affinity for water. But it is not generally recognised that the combination of water with these things may be sufficiently energetic to considerably raise their temperature. Dr. R. E. Dudgeon[2] seems to have been the first to point out that abnormally high temperatures (106° F.) might be registered in the mouth by merely wrapping some cotton-wool or the corner of a silk handkerchief round the thermometer bulb, and then forcing the expired air through this material, but he erroneously concluded that these high temperatures were attributable to the temperature of the breath, which he concluded must be higher than that of the mouth. Sir W. Roberts[3] confirmed the observations, but contested the conclusions of Dr. Dudgeon, and attributed the rise of temperature within the thermometer wrappings above that of the breath to the "conversion of latent heat into sensible heat by the rapid condensation of aqueous vapour"; and he showed that the phenomenon was rendered much more marked by previously drying the material used to surround the thermometer bulb. On the other hand, it became less and less marked when the experiment was repeated with the same strip of flannel until on the third attempt the temperature recorded was only 98 6° F. "It is probable," he says, "that with the super-exsiccated flannel the first portions of the aqueous vapour condensed at the beginning of the experiment pass from the gaseous into the solid form and constitute that portion of water which is incorporated in intimate union with all organic tissues." Dr. H. F. Parsons[4] repeated the experiments with the clinical thermometer and showed that the same action took place at a higher temperature by means of the following experiment. "A thermometer," he says, "was wrapped in a few rolls of flannel and was heated in dry air to 220° F. for some time; it was then allowed to cool a little, and as the mercury fell the index was shaken down till it stood at 212° F. The dry roll of flannel was then placed in a tin cylinder and exposed for five minutes to steam at 212° F., at the end of which time the thermometer included was found to register 239° F." Similar experiments to this have recently been made by Max Rubner, Professor of Hygiene in Berlin,[5] who has observed the temperature in the interior of a mass of wool, previously dried and warmed, rise when placed in a current of steam at 100° to 146° C. in 10 minutes, and remain above 140° C. for over an hour.

The experiments with the clinical thermometer are easily verified; cotton, paper, and woollen materials are all effective. When these are thoroughly dried and wrapped round the thermometer bulb we have frequently seen a temperature of 110° F. or more registered in the mouth of a healthy individual within a minute. It is not even necessary to dry these things artificially to register a temperature considerably over that of the mouth; and we have found the thermometer rise to 100° F. or more in the mouth when the bulb has been merely wrapped in a few turns of one's pocket-handkerchief taken direct from one's pocket, and to 102° F. in a strip of linen torn from a towel which had been hanging in the room. It is doubtless in some such way that abnormally high temperatures are occasionally produced in the clinical thermometer by persons feigning to be ill. We have also had no difficulty in obtaining temperatures considerably over 100° C. in the interior of rolls of paper, cotton, or flannel dried, warmed, wrapped round a thermometer bulb, and then placed in a current of steam.

Mr. Winter Blyth[6] considers that the heat which is evolved in the moistening of dry porous substances favours the disinfecting action of steam. But this is not generally true. It is, of course, conceivable that the heat so generated might under certain circumstances raise the temperature no higher than 100° C., in which case it would accelerate the process of disinfection; but whenever the temperature reached is above 100° C., provided that the pressure does not exceed that of the atmosphere, the steam is superheated and its sterilising action is much impaired. Our experiments have shown us that anthrax spores enclosed in the centre of a roll of thoroughly dried flannel or paper exposed to a current of saturated steam for ten minutes and more have not been destroyed, although the internal temperature of the roll has exceeded 120° C.

The following curve (Table I.) shows the rise of temperature inside a roll of flannel exposed to saturated steam at 100° C.

After 10 minutes the roll of flannel enclosing the thermometer bulb was taken out of the steam and allowed to cool. Five minutes later the thread containing spores was taken out from the centre of the roll and put into a tube of broth. A growth of anthrax bacilli on the following day showed that the spores were still living.

We will describe one more experiment of this kind because it illustrates the state of dryness of a hygroscopic substance which, after having being thoroughly dried, has been exposed to saturated steam.

A long strip of grey filter paper was weighed and then thoroughly dried in hot air and weighed again. It was found to have lost 11 per cent of its weight in the process. It was then rolled tightly round the bulb of a thermometer. In order to prevent the outer portions from becoming unduly wetted during the subsequent exposure to steam the roll was surrounded on all sides with a further quantity of the same kind of paper. The whole was then placed in a copper cylinder, in which steam was being rapidly generated at atmospheric pressure, and there it was allowed to remain for half an hour. After this the outer coverings of paper were removed and the original roll weighed again. The changes in weight were as follows Before drying the roll weighed 23 9 grammes; after drying it weighed 21·5 grammes, being a loss of 2 4 grammes, or 11 per cent.; and after steaming it weighed 21·8 grammes, being a gain of 0 3 gramme, or 1·5 per cent. The temperature in the centre of the roll rose rapidly above that of the steam and reached a maximum of 132° C in eight minutes. It remained at this point for five minutes, after which it gradually fell, so that at the end of half an hour's exposure to steam it was 128° C.

When the paper was unrolled after its exposure to steam, and in spite of its having taken up 1·5 per cent. of its weight of water, it felt perfectly dry and even crackled when crumpled Indeed, its weight showed that it had not taken up nearly so much water as it contained originally. We therefore think we are justified in concluding, with Sir William Roberts, that this 1 5 per cent of its weight of water, which it had taken up in the steaming, had entered into some form of combination with the substance of the paper and had indeed been converted into the solid state, and that the rise of temperature above that of its environment is to be attributed partly, perhaps, to the energy set free in the process of combination, but chiefly to the setting free of the latent heat, both of steam and of water That the setting free of the latent heat of water accounts for some of the rise of temperature is rendered the more probable by the following experiment The bulb of a thermometer was wrapped round with a small roll of filter paper dried in hot air and cooled over sulphuric acid When the thermometer registered the temperature of the room the paper was moistened with a few drops of water at the same temperature, whereupon the mercury rose a few degrees This rise of temperature above that of its environment, which occurs when porous organic substances are placed in steam, does not take place in asbestos which has been heated to redness and cooled over sulphuric acid It is, therefore, not a purely physical phenomenon, but depends upon some chemical combination of a hygroscopic substance with water That this combination is a loose one is shown by the ease with which the water is driven off by hot air

It is clear from the experiments which have just been related that extreme dryness may interfere with the sterilisation of such things as are composed of hygroscopic materials; and it is important to know whether such things are ever naturally dry enough for this to occur

We have already stated that a temperature considerably above the normal may be registered in the mouth if the thermometer bulb be wrapped up in the corner of one's pocket-handkerchief But we have not been able to record any temperature above 100° C in the interior of rolls of flannel, cotton, or paper exposed to saturated steam at this temperature unless these substances had been artificially dried But it must be added that these experiments were made in the damp atmosphere of an English November, and they therefore by no means show that in places and at times when the air is dryer the affinity of these things for water may not form some practical impediment to rapid sterilisation. But if this should prove to be the case the difficulty could be got over by a preliminary sprinkling of the things to be sterilised with water

In the following experiments, which were made with the object of comparing the sterilising properties of unconfined superheated steam with those of saturated unconfined steam, we made use of an apparatus constructed for another purpose which was kindly placed at our disposal by Mr H Higgins of Cambridge, the inventor It will sufficiently describe the apparatus if we say that steam generated in an ordinary boiler was allowed to pass, either directly or through a superheater composed of a series of heated iron pipes, into a long chamber. The latter was provided with a door at one end and an opening for the escape of steam at the other The means of escape for the steam were so ample that by no possibility could the pressure inside rise above that outside The superheater was placed over a gas furnace, so that by controlling the supply of gas and the rate of flow of the steam through the hot pipes it was possible to regulate the temperature of the steam and we could continually pass into the chamber either saturated steam at 100° C or steam which had been superheated to any extent desired up to a temperature at which it scorched articles of bedding which were exposed to it

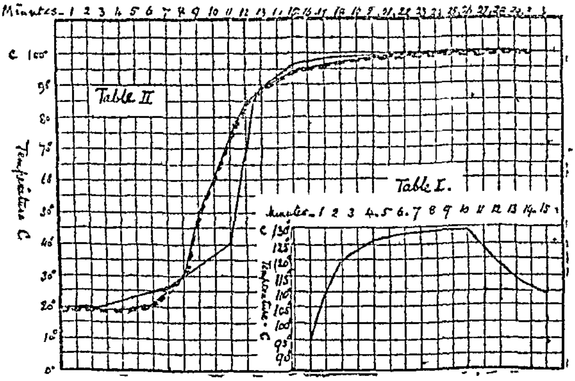

TABLE I shows the temperature inside a roll of dry flannel exposed to saturated steam at 100° C The temperature within the chamber was shown by a naked thermometer which projected through the roof of the chamber When saturated steam was used this thermometer rose in a few minutes to 99° C. or 100 C. and remained there When the superheated steam was used a temperature of 120° C was reached in five minutes 125° C in 10 minutes, and 127° C in 15 minutes After this it slowly rose to 130° C

TABLE II shows the rate of penetration of heat into a basket of tightly packed flock weighing about five and a quarter pounds when exposed to a current of saturated steam at 100° C. (continuous line) and to a current of superheated steam at a temperature of from 120° to 130° C (broken line)

III —THE PENETRATING POWER OF SUPERHEATED STEAM AT ATMOSPHERIC PRESSURE COMPARED WITH THAT OF STEAM AT 100° C INTO BULKY ARTICLES SUCH AS PILLOWS AND MATTRESSES

In our early experiments we made use of a thermo-indicator containing a piece of fusible metal which caused an electric bell to ring when the temperature reached 95° C This little apparatus was enclosed in the centre of a pillow which was then placed in the steam chamber and the time required to raise the temperature of the interior of the pillow to 95° C. was noted We were careful to use in our comparative experiments pillows as nearly identical as possible and more particularly in regard to dryness In the case of pillows which were used more than once on the same day we dried them until they regained their original weight before commencing the second experiment We used steam at 100° C and at various degrees of superheat up to 150° C, and we found that it made no difference to the rate of penetration whether the steam was superheated or not, such small differences as we

and easily explained by the fact

in

two comparative experiments that the thermo indicator should be surrounded by exactly the same amount of material.

In other experiments we watched the rate of penetration of the steam by means of a long three-foot thermometer, the bulb of which was buried in the middle of a basket of tightly packed flock, while the stem, projecting through the room of the chamber, carried the index to the outside, so that the movements of the mercury could be continuously watched. The stem of the thermometer was enclosed in a larger glass tube containing air, so that it was unlikely that any appreciable quantity of heat reached the bulb by conduction along the stem.

Experiment.—The walls of the chamber were heated to 100° C. by the passage of steam. The basket of flock was carefully weighed, packed with a maximum thermometer, the bulb of the long thermometer just described, and the electric bell fuse in its centre. Together with these was placed a thread containing anthrax spores. On the surface of the flock in the basket was another thread containing anthrax spores and another maximum thermometer. The basket was then put into the chamber, the stem of the long thermometer being put through the hole in the roof. The door was then closed and a good current of saturated steam at 100° C. passed through the chamber. The temperature indicated by the long thermometer was observed from time to time, and after half an hour's exposure the basket was taken out and weighed, the instruments having been removed, and the anthrax threads were placed in tubes of broth. The flock was then turned out of the basket and spread out on the floor. Being hot it rapidly became dry again and when collected and put back in the basket was found to be practically of the same weight and therefore just as dry as at the beginning of the experiment. Having thus assured ourselves that we were starting with the flock in the same condition as before we repeated the experiment, using superheated instead of saturated steam. Table II. shows the results of this experiment.

The rate at which the central portion of the flock was heated was practically the same in both cases, the variations shown in the table being unimportant and being probably due to some variation in the conditions which were not completely under our control. The maximum temperature reached was the same in each case—viz., 100° C. After exposure to saturated steam the basket of flock had gained three and three-quarter ounces, or 4.36 per cent. After exposure to superheated steam it weighed the same as before. In both experiments the anthrax spores exposed on the surface and in the interior of the flock were found to be dead.

It will be observed that in neither case did the temperature in the interior of the flock exceed 100° C., although the temperature of the steam to which the basket was exposed was in one case over 120° C. for 25 minutes, and this is in accordance with all our experiments in some of which considerably higher temperatures have been used and the heating has been continued as long as four hours. We believe the explanation of this curious fact to be as follows. Those substances of which our clothes and bedding are usually composed have, under ordinary conditions, a quantity of water loosely combined in the solid state with their molecules. When superheated steam comes into contact with these substances its superfluous energy is devoted to setting free, liquefying, and evaporating this combined water, and the steam becomes saturated and may be partly condensed in the process. On the other hand, when saturated steam comes into contact with these substances in a very dry state water passes from it to them and energy in the form of heat is liberated.

We may ask, What will happen when superheated steam comes into contact with these things in a very dry state? Each exerts an attraction for water and may be said to be trying to dry the other. The result will depend on the degree of dryness of the organic material and the degree of dryness of the steam. If the material is drying the steam then H_2O will be passing from the gaseous to the solid state and energy in the form of heat will be liberated in the process and the temperature will rise. But if the steam is drying the material then H_2O will be passing from the solid into the gaseous state, energy in the form of heat will be locked up in another form, and the temperature will fall to the condensing point of the steam. In any case the process, whichever it be, will continue until a balance is established between the attraction exerted by the steam and that exerted by the organic substance. As long as any excess of water remains on the side of the organic material the steam cannot remain superheated, for steam in the presence of water cannot have a higher temperature than the boiling point of the latter any more than water in the presence of ice can have a higher temperature than the melting point of ice. Thus, whether we place the pillow or other similar article in superheated or in saturated steam, the conditions within it are exactly the same. The rate of penetration of heat is therefore identical. We should consequently expect to find the sterilising effects identical also.

IV.—THE STERILISING ACTION OF UNCONFINED SUPERHEATED STEAM COMPARED WITH THAT OF SATURATED STEAM AT 100° C.

As already mentioned von Esmarch found that anthrax spores contained on threads suspended in the steam were not so easily destroyed by unconfined superheated steam at temperatures above 100° C. as by saturated steam at this temperature, and, moreover, that superheated steam did not always destroy these micro-organisms when placed on the surface of articles of bedding exposed to it. In the interior of these things they were, however, destroyed equally easily by unconfined steam, whether it was heated to 100° C. or to higher temperatures. Our own experiments confirm these statements. In all our experiments anthrax spores in the interior of baskets of flock or of pillows have been destroyed by exposure to superheated steam, as well as to saturated steam, whenever an inside temperature of over 96° C has been maintained for 10 minutes. Anthrax spores placed on the surface of the articles exposed to steam were, in all cases but one, killed, both when superheated and saturated steam were sent into the chamber. But it must be pointed out that in practice it is difficult to expose bulky articles at once to superheated steam unless these have been at first warmed and dried, for some amount of condensation is almost certain to take place on their surfaces. And in our experiments with superheated steam it may have been that the spores were destroyed, not by the superheated steam itself, but by the saturated steam in which they were for a short time unintentionally exposed.

The single experiment in which the surface spores were found to be still living was as follows. A smaller current of steam than usual was used and the temperature within the chamber rose rapidly from 92° to 143° C.; but nevertheless we found that an exposure of 50 minutes had not sufficed to destroy the anthrax spores on the surface of the pillow, although those in its interior were dead. It is probable that in this experiment the current of steam was insufficient to drive the air rapidly from the chamber and that consequently the pillow was at no time exposed to saturated steam, for even when the temperature was between 92° and 100° C., if any air remained, the pressure of the steam would never have reached one atmosphere, which is necessary to bring it up to its point of saturation at the higher of these limits.

In other experiments the very resistant spores of a micro-organism which was probably the bacillus subtilis were used. Neither saturated nor superheated steam sufficed to kill them in the interior of a pillow, though the sterilisation was continued for 10 minutes after the temperature inside had reached 96° C On one occasion the spores on the surface were found dead, but the temperature had then been so high as to scorch the surface of the pillow. In other experiments neither 20 minutes' exposure to saturated steam at 100° C. nor exposure for the same time to superheated steam at from 100° to 108° C. sufficed to destroy them.

From our experiments we feel justified in concluding that the sterilising effect of superheated steam at atmospheric pressure upon the interior of articles of bedding is identical with that of saturated steam at 100° C., but that its action upon living germs upon the surface of these things is inferior. In practice, however, it will generally happen that the surfaces of articles get a preliminary exposure to saturated steam and in a machine like that which we used this can easily be made a matter of certainty by using for the first few minutes a current of saturated steam and continuing with superheated steam for as long a time as is necessary to sterilise the interior. We may therefore conclude that as far as concerns its penetrating power superheated steam is identical with saturated steam and that its sterilising power upon the interior of porous articles of clothing, &c., is the same, and that its inferior sterilising action upon the surfaces of these things can be easily overcome. It remains to be seen whether it has any advantage in leaving articles exposed to it drier than those exposed to saturated steam at 100° C.

V.—THE DRYING PROPERTIES OF SUPERHEATED STEAM.

Current superheated steam has great drying properties. We have already alluded to the loosely combined water ordinarily present in articles of clothing and bedding and stated that superheated steam is able to drive off this water. Coming into contact with water-holding substances, the superheated steam rapidly transfers its superheat to them and becomes saturated steam. It is probable, too, that if there be much cold water present the superheated steam will even become condensed and the article rendered wetter than before. But, in condensing, the steam will part with its great latent heat and the temperature of any part of the article in question will be thereby quickly raised to 100° C. and when this point is reached the further action of the superheated steam will be to evaporate the water, both that which is held mechanically in the interstices of the substance and that which is loosely combined with the latter. Thus it is that articles submitted to superheated steam may come out lighter than before. The influence of steam in drying or wetting such things as we are considering is best shown by comparing their weight before and after exposure. Table III. gives the results of some of our experiments

TABLE III.—*Showing the Gain or Loss of Weight of Articles of Flock Exposed to Saturated and Superheated Steam.*

—	Duration of experiment (minutes)	Temperature of steam (degrees centigrade).	Weight.				Percentage loss or gain.
			Before		After.		
			lb	oz.	lb.	oz.	
Saturated steam at 100° C.	19	100	3	9¾	3	11	+2·2
	20	100	3	8	3	10¼	+4·2
	30	100	5	6	5	9¾	+4·2
Superheated steam at various temperatures above 100° C.	15	150–160	3	7½	3	6¼	−1·8
	20	170–190	3	6¼	3	5¾	−1·4
	25	120–128	5	5	5	5	0·0
	40	120–143 (mixed with air)	5	4½	4	15	−6·5
Saturated steam 13 minutes, followed by superheated steam 17 minutes	13	100	3	9	3	9½	+0·9
	17	100–144					

These results show that superheated steam may be relied upon to leave articles of bedding exposed to it for a sufficient length of time drier than before, and that the length of time necessary to attain this result is in the case of those articles which ordinarily require sterilisation not inconveniently long.

Note on the anthrax spores used in these experiments.—The anthrax spores were obtained from a culture which killed a mouse in 30 hours. They were scraped off on agar tubes and suspended in sterile salt solution of 7 per cent. Threads of silk and cotton, previously washed in distilled water and sterilised, were then placed in the suspension of spores, taken out and dried over sulphuric acid for 24 hours. Their powers of resisting heat were tested as follows: Threads were placed in a chamber full of steam at 100° C for one, two, three, and four minutes respectively, then placed in beef broth and incubated at 36° C. In No. 1 alone a growth took place, the others remained sterile. A thread dropped in boiling broth which was rapidly cooled gave a culture. A thread dropped into boiling broth and boiled for half a minute gave a culture. A thread dropped into boiling broth and boiled for two minutes gave a culture which, however, grew very slowly, no growth being apparent until the third day

---

BRISTOL ROYAL INFIRMARY.—The committee of this institution recently offered to make 24 beds available for soldiers of the Gloucestershire Regiment invalided from South Africa and requiring active medical or surgical treatment. The War Office has accepted the proposal.

LANGPORT DISTRICT COUNCIL.—At the meeting of the Langport District Council held on Jan. 16th a letter was read from the Somerset County Council asking what steps were being taken to provide an isolation hospital. One of the members stated that there was not so much disease by one half as there was 20 years ago and that "it was the half-crown notification fees that accounted for the number of cases" Eventually the clerk was instructed to inform the county council that an isolation hospital was unnecessary.

SEPTIC LYMPHANGITIS ALONG THE URETERS AFFECTING THE KIDNEYS TREATED WITH ANTI-STREPTOCOCCIC SERUM; RECOVERY.

BY J. W. STENHOUSE, M.B., C.M. EDIN., M.R.C.S. ENG., L.R.C.P. LOND.

ANTI-STREPTOCOCCIC serum is still in the experimental stage. Negative results are numerous and a positive result is therefore of interest. The case about to be recorded was not a hopeful one and as a last resort the serum was tried very much in the nature of an experiment. The coincidence of the combination of quinine in the treatment is perhaps worthy of attention.

A married woman, aged 28 years, gave birth to a child seven years ago and made a very fair recovery. She had a "whitish" discharge for two years when it became "yellow-like matter" and increased to such an extent that it gave her a great deal of discomfort and pain on walking (I may here interpolate that the husband denied ever having had any venereal complaint). This discharge went on for a couple of months when she consulted a gynæcologist who discovered that she had also a urethral discharge which could be expressed on pressure of the anterior vaginal wall. She was treated with astringents to the vagina and urethra and sandal-wood oil internally. She carried on this treatment for above five years, during which time the urethra was additionally treated with numerous drugs, but without any effect. The vaginal discharge was kept in check with the astringents and she could get about with tolerable comfort. About Whitsuntide in 1899 she used protargol for the urethra, and shortly after she had begun to use it she developed cystitis which lasted for a month. The urine, however, never properly cleared. On July 20th she went into a home to have the urethra treated and had Skene's tubules split open and cauterised. On the 26th she began shivering, had a sore throat, and pains in her limbs. She left the nursing home on the following day. As the throat did not improve she sent for me, but as I was away for my holidays Dr. E G. Yonge kindly saw her. He was of opinion that she was suffering from septic tonsillitis and treated her for five days with iron and quinine internally and carbolic locally.

Bicycling had been recommended to this patient for her uterine condition, so she resumed that amusement about August 17th. On the 20th she went for a run of 29 miles and on her return in the evening she began to shiver and developed another attack of cystitis. She was able to be out of bed on the following day but in the evening she had a rigor with pains in the limbs and in the right side of the abdomen and back followed by sweating. The rigors were very frequent during the night and were repeated during the day. She was now confined to her bed and unable to sit up in it. I was called to see her on the evening of the 22nd. The pulse was 116 and the temperature was 104° F. Her face was pinched and the skin had a dirty greyish look. The abdomen was slightly distended and the muscles on the right side resisted pressure while those on the left were tolerably flaccid. The kidney on the right side was easily palpated; it could be felt to be enlarged and was very tender. A line of tenderness ran along the line of the ureter and on pressing it over the brim of the pelvis it could be felt as a thickened cord and the pressure gave much pain. The urine had a cloud of pus and there was pain at the end of the act of micturition. The cervix uteri was in a condition of ectropion and the uterus was retroflexed. The heart and lungs were normal. I prescribed 10 grains of salol every four hours and a mixture containing boric acid, buchu, hyoscyamus, and uva ursi. The next morning her pulse was 94 and the temperature was 101·8°. During the night she had only modified rigors which produced a sensation of cold followed by one of heat. The right kidney was as tender as on the preceding evening and slightly larger. She kept very much in the same condition all that day and the following, the temperature oscillating between 99·8° and 102°. On the 25th the right kidney was larger; it was close to the abdominal wall and [illegible] the af[illegible] of this ureter to the kidney and by the evening the left kidney could be easily palpated and was also tender. Some enlarged glands could be felt about the iliac arteries.

I called Mr. J. Collier to see her in consultation. He confirmed the diagnosis and we thought it had gone on to suppurative nephritis. The prognosis was grave indeed. Mr. Collier suggested that quinine should be tried (five grains every four hours) and urotropine (10 grains three times a day). On the following day the left side was worse and the patient was losing ground. Her face was more earthy-looking and she was rapidly losing flesh and strength, so much so that she could hardly move in bed, apart altogether from the pain which any movements caused her. As the prognosis was so bad I thought that the serum treatment held out a ray of hope and in any case if it did no good it could not make her worse than she was, so, with Mr. Collier's approval, I determined to make a trial of it. I therefore stopped the quinine and injected into the left flank about 20 cubic centimetres of serum. This injection and the subsequent three were made with all antiseptic precautions, the syringe being boiled and the hands and skin being thoroughly washed and carbolised. The next morning the pulse and temperature had both fallen, the former from 96 to 80 and the latter from 102·2° to 98·2°. This was encouraging. The serum had modified the pulse and temperature more than the drugs. In the evening there was a rise in the pulse to 90 and in the temperature to 101·2°, so I injected 10 cubic centimetres of serum into the right lumbar region. Instead, however, of getting the expected fall next morning the pulse and temperature had both risen, the pulse to 100 and the temperature to 103°, and at 8 P.M. the pulse had further risen to 108 and the temperature to 102·4°. I resumed the quinine every four hours and injected 20 cubic centimetres of serum into the left lumbar region. On the 29th, at 8 A.M., the pulse was 84 and the temperature was 99·8°; at 4 P.M. the pulse was 84 and the temperature was 101°; and at 8 P.M. the pulse was 84 and the temperature was 99·4°. 20 cubic centimetres of serum were injected into the right flank. On the 30th the pulse was 68 and the temperature was 98°, and it remained normal all day. The patient was feeling better and the pains were diminished. On the 31st there was a slight rise of the pulse (to 80) and of the temperature (to 99·8°). On examination I found the left pupil slightly smaller than the right and somewhat oval in shape. She had no headache, but said there was "a slight mist over the left eye." Percussion of the abdomen showed the spleen to be normal in size. The enlargement of the right kidney was diminished, the tenderness was less, the ureters were not so tender, and no glands could be palpated. On Sept 1st there was a slight rise of temperature from normal to 99·2°. The left pupil was slightly irregular, the iris was retracted at the upper and inner quadrant, and both kidneys and ureters were less tender. At the seat of injections on the right and left sides there were two extensive patches of erythema which gave the patient great discomfort, especially at night, when it rose up in wheals like urticaria. The intolerable itching was most difficult to control; but what gave most relief, after trying various remedies, was an ointment containing hydrocyanic acid, carbolic, and chloroform in lanoline. On the 2nd the pulse was 60 and the temperature was 97·4°. On the 3rd the right kidney was much smaller and the abdomen could be more freely palpated without giving much pain. The pupils were normal. The urine was much better but there still remained the urethral discharge. On the 6th I dilated the urethra with Hagar's dilators till I could get my small finger into it but could feel nothing abnormal, either cicatrices or pouching. The dilatation did good, however, as the discharge from Skene's tubules on one side dried up, while that on the other became serous. The temperature and pulse remained normal during the week until the 11th, when there was a slight rise of the pulse to 82 and of the temperature to 99·2°. Coincident with the rise there was pain in the left leg; the glands in the groin, which had previously been slightly enlarged, were now tender on pressure; there was pain along the line of the femoral artery; the veins in the calf of the leg were enlarged and cord-like; and there was slight œdema of the leg and foot. The thrombosis was treated with elevation of the limb and lead and opium fomentations and the glands with iodine ointment and carbolic compresses, and the condition had practically disappeared by the 20th. The patient felt perfectly well and had put on flesh. The foot required to be bandaged as it became slightly swollen with use. The urethral discharge remained. Five months after the patient stated that she had not felt better for years.

Remarks by MR. J. COLLIER.—On examination of this patient I came to the diagnosis mentioned by Dr. Stenhouse above, mainly from the thickened condition of the ureters. The prognosis seemed to be the very gravest, for the general condition was so extremely bad as to make it appear certain that the kidneys were riddled with small abscesses. The further history of the case after it was seen by me points sufficiently to the general pyæmic state. Dr. Stenhouse and I agreed at once as an alternative treatment to inject the anti-streptococcic serum, and this was done with a surprising and most satisfactory result. Since the above case in two equally desperate cases—one an adult and the other a child who was apparently dying at the Pendlebury Children's Hospital from acute general pyæmia—I have been delighted with the result of the administration of full doses of quinine associated with repeated serum injections.

Manchester.

THE TREATMENT OF IMPERFORATE RECTUM: AN ANALYSIS OF TEN CASES, IN NINE OF WHICH COLOTOMY WAS PERFORMED.[1]

BY W. P. MONTGOMERY, M.A. OXON., M.B., B.S. LOND., F.R.C.S. ENG.,

SURGEON TO THE CRUMPSALL HOSPITAL AND TO THE ANCOATS HOSPITAL, MANCHESTER

DURING the last few years I have operated upon 10 cases of imperforate rectum. The series is unusual in length and some of the cases present special points of interest. I am much indebted to the honorary surgical staff of the Manchester Royal Infirmary, where the majority of the cases were seen, for permission to record them.

The accompanying table gives a brief account of the cases. The last case on the list does not illustrate any of the points to which I wish to call attention and I leave it out of consideration altogether. Three of the children were sent home to their mothers immediately after operation. Two of these are alive; the other died five days later and no post-mortem examination could be obtained. The other six died in hospital and were all carefully examined after death.

Operation.—The two considerations influencing the choice of operation were: (1) the size of the pelvic outlet; and (2) the general condition of the child. In no single instance was any bulging of the perineum during crying made out. One case had been unsuccessfully explored with the trocar before I saw it. In three others an attempt was made without success to find the gut by the perineum after a resection of the coccyx. In the other five immediate colotomy was performed on the left side. The incision was made an inch below and internal to the anterior superior spine. The small gut presented in five cases, the cæcum in three cases, and the sigmoid in one case. In this and one other case only was distension of the sigmoid and rectum at all marked. There was considerable difficulty in bringing the gut up to the level of the abdominal wall in all of the six cases in which the cæcum did not present. This was apparently due to the great distension of the small gut and the cæcum and not to any shortness of mesentery. In eight cases the gut was simply fixed to the muscle and fascia by sutures passed through its outer coats. It was then opened and further fixed by four sutures transfixing the whole thickness of the gut wall and including the skin. The difficulty in bringing the loop well up out of the abdominal cavity prevented the application of any supporting mesenteric suture except in one case. In this an attempt was made to fix the gut according to a plan which I have found very successful in the adult and which I hope shortly to record. This was with a view to lessening the great tendency to prolapse in these cases. The child, however, suffered from congenital heart disease, which was most embarrassing during the operation and led to death on the third day. This tendency to prolapse has been observed in nearly all recorded cases of recovery after colotomy and was quite marked in both of my cases. It is a necessary result of the difficulty in bringing up the sigmoid loop and the consequent inability

---

[1] A paper read before a meeting of the Manchester Medical Society on May 5th, 1899.

SYNOPSIS OF TEN CASES OF OPERATION FOR IMPERFORATE RECTUM.

No.	Sex.	Age.	Operation.	Result.	Remarks.
1	M.	Three days.	Immediate colotomy.	Death on fourth day.	There was no proctodæum. Exploration by trocar had been performed before the case was seen. Necropsy.—The whole rectum was replaced by a fibrous cord four inches long passing to the prostate and the base of the bladder. There was much old hæmorrhage in the pelvis.
2	M.	Four days.	Immediate colotomy.	Alive, age 18 months.	There was no proctodæum. The patient was sent home immediately after operation.
3	F.	Three days.	Immediate colotomy.	Alive, age two years.	The proctodæum was half an inch deep. The patient was sent home after operation.
4	M.	Three days.	Colotomy after perineal exploration.	Death in five days.	There was no proctodæum. The cæcum presented much distended and dil coloured and was opened. The sigmoid could not be found on the left side. The patient was sent home to the parents. No necropsy was held.
5	M.	Two days.	Immediate colotomy.	Death in three days.	No proctodæum was present. Necropsy.—The pouch descended to three quarters of an inch of the skin. There were patent auriculo-and ventricular septa.
6	M.	Five days.	Immediate colotomy.	Death in seven days.	The proctodæum was half an inch deep. The cæcum presented and was opened. Necropsy.—The sigmoid loop passed over to the right iliac fossa.
7	F.	Two days.	Colotomy after perineal exploration.	Death in three days.	The proctodæum was half an inch deep. Necropsy.—The gut three quarters of an inch above the proctodæum was attached to the upper end of the vagina.
8	M.	Three days.	Colotomy after perineal exploration.	Death in 17 days.	There was no proctodæum. Prolapse of the small gut through the abdominal wound occurred on the twelfth day. Necropsy.—The gut one inch from the skin was fixed to the prostate and the base of the bladder.
9	M.	Two days.	Immediate colotomy.	Death in three days.	There was no proctodæum; the sigmoid and rectum were distended. Necropsy.—The gut was three quarters of an inch from the skin.
10	F.	One month.	Perineal dissection and plastic operation.	Alive, age six months.	The rectum was imperforate; there was a small gradually closing recto-vaginal fistula. The rectum was opened at the perineum and the fistula was closed.

to pass a supporting suture through the mesentery. However, with a well applied pad the inconvenience did not seem great. One further point requires notice, which is that the tendency to peritoneal repair in these small children does not seem great. One lived seven days and another 17 days, yet it was found at the post-mortem examination that the line of union fixing the gut was in each case very thin. In one case the sutures gave way on the twelfth day and some inches of small intestine prolapsed. The coils were cleaned and reduced and the child lived five days longer, yet there was no sign of any adhesion in these coils after death. The suture of the gut to the abdominal wall ought to be especially carefully performed.

Pathology.—Six of the cases were carefully examined at the necropsy with a view to proving the case or otherwise of the perineal operation. Allowance need not be made for any distension of the blind end, for in only two of the whole number of cases was distension of the sigmoid and rectal pouch at all marked. In one case the rectum was entirely wanting, a fibrous cord four inches long descending from the termination of the bowel in the iliac fossa to be attached below to the base of the bladder. In three cases there was no proctodæum. The pouch descended to distances of one inch, three quarters of an inch, and three quarters of an inch respectively from the skin and ended in a thick mass of fibrous tissue connected with the prostate and the base of the bladder. In two of these cases the pelvis was very narrow, both laterally and antero-posteriorly, and a resection of the coccyx would hardly have given sufficient room for the successful opening of the gut at the perineum. In the other an attempt had been made to find the blind end after a resection of the coccyx. The pelvic outlet was comparatively large, but the exploration had been confined, as we are advised it should be, to the concavity of the sacrum, and the pouch, which was one inch from the surface, was passed by. In two other cases there was an anal cul de sac of over half an inch in length, the gut cavity ending half an inch and three quarters of an inch respectively above this. In one of these the perineal operation had been tried. The pelvic outlet in each case was very narrow; in one the blind end was far forward fixed to the upper end of the vagina and cervix, and in the other it was fixed to the region of the prostate.

Abnormal position of the sigmoid flexure.—In two cases (Case 4 and Case 6) the sigmoid could not be found in its normal position. The cæcum presented itself much distended and was opened in the left groin. In Case 4 the flexure, hardly distended, could be felt passing over to the right side above the pelvic rim. The child was sent home and no post-mortem examination could be obtained. In Case 6 a similar condition of the parts existed and at the necropsy the flexure was found in the right iliac fossa. These children lived five and seven days respectively with their cæcal openings. These two cases illustrate Huguier's[2] suggestion that in cases of imperforate rectum it is better to look for and to open the sigmoid in the right groin. Giraldès[3] found the sigmoid on the right side 20 times in 134 cases and quotes Bourcart as having found it 30 times in 150 cases of newly born children. Including the nine cases above mentioned I have examined the bodies of 20 newly born infants for this abnormality. In six of these it is possible that the sigmoid might have been missed in the operation of left inguinal colotomy. This includes my two cases in which it certainly was missed. These two cases are interesting in another way, for they point to one of the causes of failure after the rectum has been found and opened at the perineum. In Case 6, where the patient was five days old at the time of operation, the cæcum was extremely congested and distended and so twisted on its mesenteric axis as to give rise to a volvulus. The acute obstruction was certainly at that point and not at the rectal imperforation, for the sigmoid was almost undistended. In Case 4 the condition was similar but not so acute. The right course in each seemed to be the relief of symptoms of acute obstruction by opening the cæcum.

Conclusions.—Before deciding on the relative merits and demerits of the perineal and iliac operations they must be considered (1) as urgent operations for acute obstruction; and (2) as methods of permanent relief. The careful analysis of these cases points to certain limitations in the perineal operation from a life-saving point of view. In Curling's[4] tables out of 57 cases of the type we are now considering the gut was not found on perineal exploration in 23. Owen[5] did not find it in four cases out of five. Excluding the two cases of recovery and the one death in which no post-mortem examination was obtained, of the six cases carefully examined I could only have been reasonably sure of finding the gut in two. These feeble children are in no sense the proper subjects for prolonged operation. Further, as two of the cases seem to show, the acute obstruction is often in the cæcum and will have a better chance of relief if treated by the abdominal route. The fact that there is considerable difficulty in the finding of the gut and a possible chance that an opening in it at the perineum may not relieve the obstruction is decided evidence in favour of routine colotomy in these cases.

The operations may be compared as methods of permanent relief. We hear much of the terrible condition of the individual with an acting anus in the groin; but it must be remembered that the alternative is not a controllable anus near its normal situation. I should be inclined to say that an inguinal anus is more comfortable and more easily attended to than a perineal anus. Further, the majority of children who recover from the perineal operation need almost constant attention to prevent stricture of the new passage. In Carling's tables out of 26 cases in which there was no proctodæum (the worst form) five lived long enough to be called cures, but the author could only call one a real success. All the others suffered from more or less pronounced stricture-incontinence. Of 31 cases with a proctodæum 10 were called successful, but many were mild cases with a mere membranous diaphragm between the two parts of the bowel. A case reported by Walford[6] is much to the point. The patient died at the age of 17 years from ulceration and perforation of the sigmoid above a perineal anus made a few days after birth. Owen in two cases tried some time after colotomy to make a perineal anus by cutting down upon a sound passed through the colotomy wound. Both children died, but Maylard[7] and Goëde[8] have recorded successes. We are probably justified in saying that if more than half an inch separates the rectal pouch from the surface a perineal anus will be a continual source of trouble. Even viewed in the light of the series collected by Ourling, Cripps, and Anders the evidence of my cases seems to support the argument that on most accounts immediate colotomy is the preferable operation.

BIRMINGHAM GENERAL HOSPITAL.

A CASE OF FIBRO-MYOMA OF THE UTERUS; LEFT HYDRO-SALPINX; CARDIAC DILATATION AND DEGENERATION; TOTAL ABDOMINAL HYSTERECTOMY; DEATH ON THE TENTH DAY FROM PERFORATION OF A LATENT DUODENAL ULCER.

(Under the care of Dr. THOMAS WILSON.)

THE serious influence exerted by abdominal tumours on the heart is often overlooked. Hofmeier in 1884 collected 18 cases of tumour of the abdomen in which sudden death occurred from heart-failure, and in all of these there was degeneration of the heart fibre. Penrose[1] attributes the change in the cardiac tissue to the increased blood-pressure which is always present in abdominal tumours. This serious effect is an additional argument in favour of early operation in these cases. The perforation of the duodenal ulcer in Dr. Wilson's case was an unfortunate accident which no care could have guarded against.

A thin, spare widow, aged 42 years, was first seen on Dec. 14th, 1897, when she complained that for six months there had been pain in the right lower abdomen and discharge from the vagina. She had had one child 22 years before and no other pregnancies; her husband had been dead for 16 months. A firm multi-nodular fibroid of the uterus of the size of a fœtal head occupied the hypogastric region and extended to within two inches of the umbilicus. The catamenial periods began at the age of 15 years, had occurred regularly once a month, lasting a week, and had been preceded for a day and accompanied during the whole of the flow by a dull, aching sacral pain. The beginning of the present illness was marked by a profuse period lasting 14 days and confining the patient to bed, and for the past six months the periods had been very irregular, usually recurring about every three weeks, with varying but not on the whole increased flow. For the same time there had also been yellow discharge, clearer in appearance and more profuse just before the periods.

On Oct. 25th, 1898, the patient was rather thinner and paler than before and the fibroid appeared to be of about the same size. There had been no menorrhagia, but the yellow discharge had been profuse and the pain severe. The cardiac impulse was much diffused over an area extending to three-quarters of an inch outside the left nipple line and to about one and a half inches below it; the impulse was forcible and deliberate but not distinctly heaving. A soft systolic murmur was heard all over the cardiac area, best at the lower end of the sternum and at the base, especially over the aortic cartilage. There had been palpitation and shortness of breath for about two years; previously the woman had been quite well and she had never had rheumatic fever.

In April, 1899, the patient was obviously losing ground and had become rather thinner and distinctly more anæmic. Paroxysmal stabbing pains, not constant and better in bed, were felt in the lower part of the back and in the lower abdomen, especially in the right inguinal region. The pains doubled the woman up and were sometimes followed by vomiting. The periodic losses and the discharge continued to be about the same; the fibroid had apparently somewhat increased in size; the cardiac signs were more marked, the impulse being now more diffused and extending to one inch outside the nipple, and being also distinctly less forcible and more slapping in character. For about two months there had been occasional nausea and on a few occasions actual vomiting after food. The patient was admitted to the General Hospital on April 22nd, 1899, and on the 25th the tumour was removed by total abdominal hysterectomy.

The usual median lower abdominal incision was made. Much difficulty was experienced in delivering the tumour because of numerous firm membranous adhesions between its posterior surface and the front of the rectum and sigmoid flexure: some of these adhesions required to be divided by the knife and scissors. The left tube was closed and distended with clear fluid, some of which escaped into the peritoneal cavity. The peritoneum was exceedingly thin; the omentum, fine and transparent, with almost no fat, was torn a little, and a considerable portion was removed at the end of the operation. After the tumour was delivered the left ovario-pelvic ligament and the left round ligament were successively tied and divided between pairs of fine silk ligatures; the upper part of the right broad ligament was treated in the same way; the bladder was then stripped down and the vagina was opened into the anterior fornix. The uterine vessels on each side were now secured and the tumour was cut away. One or two small bleeding points were secured with thin silk; the peritoneum was then sponged out and a strip of gauze was pulled down from above into the vagina and left with its upper end in Douglas's pouch; finally, the abdominal wound was closed with deep silkworm gut sutures. During the operation the patient became much collapsed and received twice four minims of strychnine solution by hypodermic injection, saline infusion under the skin of the axilla, and finally intravenous transfusion of saline fluid.

The tumour removed weighed 2 lb. 3 oz. and consisted of the uterus with numerous fibroids affecting its body and of both sets of appendages. After being hardened in formalin it measured 13·5 centimetres in length, 11 centimetres in width, and eight centimetres in the antero posterior direction. The cavity of the body measured five centimetres and was distended by a submucous fibroid growing from the fundus and measuring 4·5 by 3·75 centimetres. In the fundus and anterior wall were numerous interstitial fibroids measuring from three centimetres to 0·5 centimetre in diameter, and there were also many small subperitoneal fibroids. On the median section about 10 tumours were cut through and showed the usual whorled appearance and bright silvery sheen. The cervical canal measured 3·5 centimetres and the cervix was free and normal. There were numerous old adhesions about the tubes and ovaries, especially on the left side. The left ovary was much enlarged, the right ovary contained a distinct Graafian cyst, the diameter of which was larger than the rest of the organ, and a recent corpus luteum at the outer end. The left tube had been distended with clear watery fluid, and its peritoneal ostium was closed with withdrawal of its fimbriæ into the lumen. The right tube was shortened and on section showed an empty, small, and extremely tortuous lumen; the walls were not thickened; the folds were distinct and not thickened; the fimbriæ were covered by a thin membranous layer continuous with the peritoneal and muscular coats of the tube.

Two hours after the end of the operation the patient had a fair radial pulse of 100 and in seven hours she was looking well and had a good pulse of 108. There was vomiting several times the last four hours after the operation; urine was passed naturally seven hours and flatus 18 hours after the operation. Hypodermic injections of strychnia solution and saline enemata were ordered and gradually left off as the patient improved. On May 1st it was noted that the apex beat was in the fifth space in the vertical nipple line; the systolic murmur was softer in character, but was still heard all over the cardiac area. The condition of the patient gave rise to no anxiety until the ninth day after the operation; on the morning of that day at Dr. Wilson's visit the woman was looking well. In the afternoon of the same day she did not appear to the ward-sister to be quite so well; a dose of castor-oil at 8 P.M. was followed by severe pain in the epigastrium which was promptly relieved by hot fomentations; pain became very severe afterwards in the lower abdomen, especially on the right side of the wound. The pulse began to run up and in the course of the night increased from 120 to 156 beats to the minute. On the next morning (May 4th) Dr. Wilson was called to the patient at 5 A.M. and found her in a state of collapse and complaining of pain in the lower abdomen; the pulse was 156 and the respirations were 36 to the minute. The limbs were becoming cold and there was profuse perspiration all over the body. There had been no vomiting and there was no distension of the abdomen. The wound was perfectly healed and the packing which had been removed from the vagina was sweet and merely moist. In spite of the free use of stimulants the patient rapidly sank and died at midday, 16 hours after beginning to be ill.

Necropsy.—A post-mortem examination was made at 11 A.M. on May 5th by Dr. Stuart Macdonald, to whom Dr. Wilson is indebted for the following notes. The abdomen was a little prominent. The operation wound was firm, dry, and healthy; after opening the abdomen the wound was found to be free from adhesions and there were no stitch abscesses. On opening the abdomen some gas escaped from the peritoneal cavity and there was a distinct gastric odour. There was general suppurative peritonitis, most marked in the upper abdomen; some sour-smelling fluid, milk curd, and partly digested bread were found free in the peritoneal cavity. The omentum was covered with flabby lymph and was adherent to the right pelvic brim. The stomach was contracted and there were large tracts of fine recent adhesions over both its surfaces, as well as over both the upper and lower surfaces of the liver. On raising the stomach fluid was seen to escape from a perforation of about the size of a sixpenny piece on the posterior wall of the first part of the duodenum about half an inch beyond the pylorus. The ulcer had rather thickened smooth edges and appeared to have been adherent to the head of the pancreas. There was no other ulcer in the alimentary tract and there was no post-mortem digestion of the stomach wall.

The vermiform appendix was adherent by plastic lymph to the upper part of the stump of the right broad ligament. The uterus and its appendages had been entirely removed. There was a little extravasated blood in the stump of each broad ligament, rather more on the left side, but the operation wound looked perfectly healthy and there was free drainage per vaginam. The broad ligaments were adherent by plastic lymph to the surrounding parts; a small amount of flaky fluid was present in Douglas's pouch, but there was no free blood. The liver was extremely fatty; the pancreas and spleen were healthy. The kidneys both showed fatty degeneration and in the right kidney were numerous small cysts in the cortex, medulla, and pyramids; the capsule, however, stripped easily and the cortex was not markedly diminished. There was œdema of the upper lobe of each lung and some passive congestion of both bases was observed.

The pericardium contained about two drachms of clear fluid; there was a fair amount of pericardial fat; no adhesions were present. The right auricular appendix contained some small ante mortem clots; the left was two inches long and had a very small lumen in three-quarters of its extent. There was a little atheroma of the aorta with some thickening of the cusps of the valve, and small patches of atheroma surrounded the orifices of both coronary arteries. The openings of both the coronary arteries were rather patulous, the right being especially so, and the latter was somewhat dilated throughout, but showed no atheroma. The aortic valve was competent; the cone diameter measured 0·9 inch. The pulmonary valve was competent, the cusps were healthy, and the diameter was 1·5 inches. The mitral valve measured 1·28 inches; it showed evidence of slight chronic endocarditis at the base of the anterior cusps. The margins of both the cusps were slightly nodular and there were no vegetations. The tricuspid valve, similar in appearance to the mitral, measured 1·4 inches in diameter. The heart-muscle was soft and flabby and was uniformly brown in colour, with a somewhat hyaline appearance. There was no obvious fatty degeneration. The left ventricle was three and a quarter inches long and the right was four and a quarter inches. The wall of the left ventricle was 1·4 centimetres in thickness all over; that of the left auricle was 0·6 centimetre; that of the right ventricle was 0·85 centimetre and of the right auricle 0·5 centimetre. Under the microscope the heart muscle showed some brown atrophy with slight fatty degeneration of the fibres. The organ weighed nine and a quarter ounces and contained extensive post-mortem clots in all the cavities, with a few ante-mortem clots in the right ventricle.

Films from the peritoneal exudation showed great numbers of micro-organisms of various kinds: large bacilli, small bacilli resembling bacterium coli, diplococci, streptococci, and a few staphylococci. Cultures were rapidly overrun with growth and the organisms were not differentiated.

Remarks by Dr. WILSON.—The above case is worthy of being placed on record for two reasons—in the first place because of its sudden and unexpected catastrophe and in the second because of the serious heart disease which was present in a patient suffering from fibro-myoma of the uterus. Sudden rupture of a latent intestinal ulcer in the course of convalescence from a severe operation on the uterus forms a rare but not unique coincidence, at least two examples having been previously recorded. Professor A. R. Simpson[2] is stated to have shown the specimens from a case of perforation of a duodenal ulcer following myomectomy; and Dr. Harris,[3] speaking of deaths from Cæsarean section, &c., says: "Even peritonitis has been found on autopsy to be entirely independent of the operation or the parturient state; as, for example, where it was produced by a perforating ulcer of the intestines, cicatrices of previous ulcers being found, as in the third case of Professor Chiara of Florence, Italy, operated upon Jan. 5th, 1888."

In such a case as the above it is of course easy to be wise after the event, and on looking back upon its history several symptoms are found noted which may possibly have been due, wholly or in part, to the presence of a duodenal ulcer. Such symptoms are the nausea and vomiting after food which occasionally occurred in the last two months of life, and to some extent also the wasting and anæmia which had progressed very rapidly in the same time. None of these symptoms were very obtrusive and most of them had been gradually progressive, while the pains complained of continued to the last to be experienced in the same positions as those which had so long tormented the woman—namely, in the sacral region and in the lower abdomen, especially on the left side. The whole of the very serious and progressive change in the patient's condition appeared fairly to be explained by the presence of the fibroid tumour of the uterus and by the accompanying heart disease.

The second point of interest is one of the highest importance and raises the question of the relation between the affection of the cardiac walls and the growth of fibromyomata of the uterus. The relation is in my opinion one of causation, the dilatation and degeneration of the heart having been in some way set up by the growth of the uterine tumours. The frequency of serious heart affections in cases of fibroids is in my experience considerable and calls for more consideration than it has hitherto received. A fibroid may give rise to heart affection by reason of the anæmia which is often present or in a more direct but less easily understood manner by setting up hypertrophy that only later leads to dilatation and degeneration. A somewhat analogous relation to the latter may be found in the hypertrophic dilatation of the heart that arises during pregnancy, but there is the important distinction that the causing condition in this latter case is of *definite duration*, whereas in the case of the fibroid the duration is indefinite. The question of the connexion between the affection of the heart and that of the uterus has an important bearing upon the treatment of the latter. If the affection of the heart in any case appears to have arisen as a consequence of the growth of the uterine tumour, and if it is progressive in spite of medical treatment, the condition of the heart becomes an urgent indication for the removal of the tumour by operation.

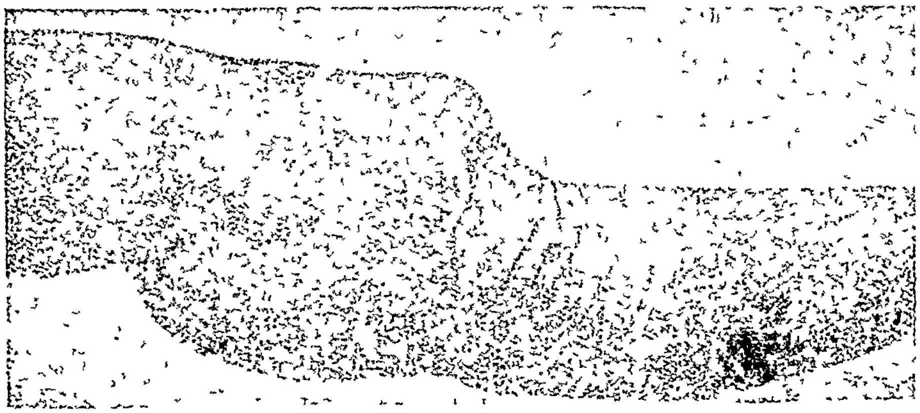
PENRHYN QUARRY HOSPITAL, BETHESDA.

A CASE OF DISLOCATION OF THE HEAD OF THE TIBIA BACKWARDS, UPWARDS, AND INWARDS, AND OF THE PATELLA UPWARDS AND OUTWARDS

(Under the care of Dr E. A. MILLS-ROBERTS)

THERE are few dislocations which are more rare than those of the knee. The ligaments of the joint are so numerous and so strong that a fracture is much more likely to occur than a dislocation. In the dislocation upwards and backwards of the tibia the posterior ligament, and at least the posterior crucial ligament, must be ruptured The popliteal vessels are very likely to be compressed by the displaced tibia or they may be torn completely across. Reduction is usually easy, but cases have been reported by Bagnall-Oakeley[1] and by Karewski,[2] in which, although reduction was not effected, very fair movement at the knee-joint remained. In one case of irreducible dislocation Spence[3] opened the joint and was able after division of the external lateral ligament to get the bones into position, a useful limb remaining Dr. Mills-Roberts's case is remarkable for the great amount of displacement and for the very satisfactory movement which resulted.

A man, aged 55 years, was admitted into the Penrhyn Quarry Hospital on May 24th, 1898. On examination he was found to be suffering from a complete dislocation of the right leg backwards, upwards, and inwards, the patella being displaced outwards and upwards. (The illustration gives a very good idea of the appearance of the limb on admission) There was a severe laceration of the skin about the middle of the leg, on the inner aspect The left shoulder, back, left thorax, and left thigh were badly bruised on the next day these parts were severely ecchymosed. His left thumb was also lacerated. The patient gave the following history. He was employed at his usual work of a "slate miner" at the Penrhyn Slate Quarries, working on the "face" of the rock between two galleries, the distance between the galleries being 54 feet. Having fastened himself to the usual rope he was removing some loose slate from the "face" of the rock about nine feet below the surface of the upper gallery. He would thus be fastened to a rope nine feet in length and his position would be much of the nature of a pendulum. While thus employed some loose *débris* "ran" and struck him on the left side and back, swinging him free of the rock. On his return he was again struck on the left shoulder and again swung free of the rock. On his second return his foot and leg caught between two stones; at the same time more *débris* came down and struck him on the back and shoulder, on this occasion jerking, as it were, the body free of the leg that was caught and giving rise to the above condition. The appearance of the boot and leg verified the history of the accident. On admission the limb was found to be extended with an appearance of being bent forwards (*vide* illustration). The skin about the injured parts was perfectly normal in appearance, there being no sign of any abrasion or injury of any kind. It was tensely stretched over the condylar end of the femur, the whole of the articular surface being quite distinct. The absence of the patella from its normal position was perfectly evident to the naked eye. The rounded shape of the external condyle was very distinct, the internal condyle being less so The skin below the lower end of the femur appeared in well-marked folds and wrinkles (*vide* illustration). On the inner aspect of the leg, about the middle and to the inside, there was a laceration (with a deep puncture) about two inches long. The foot was everted. About four inches above and behind the condyles on the posterior aspect of the thigh was a well-marked swelling in which the head of the tibia could be made out (*vide* illustration) The patella was easily recognised displaced outwards and upwards.



Reproduction of a photograph of a sketch of the leg

With the assistance of Mr. Pritchard Roberts the patient was anæsthetised. When well under, Dr. Mills-Roberts flexed the hip and applied extension to the leg in the axis of the limb. The dislocation was easily reduced. After reduction the sensation of holding the leg was as if the knee-joint was a mass of flabby jelly, a feeling never to be forgotten There was a little difficulty in reducing the patella, the first attempt at tilting being a failure; however, it readily and easily went over on the second attempt Dr. Mills Roberts put him up on a long posterior splint, applying evaporating lotions for three weeks On May 25th there was a good deal of swelling, but it was rapidly amenable to treatment. On June 15th Dr Mills-Roberts felt justified in removing the splint and in beginning passive movements and massage. This treatment was continued till July 6th. The movements were done with the greatest care and gentleness, and on the least sign of inflammation were discontinued for a day or two. On July 6th the patient had full flexion and extension and was dismissed with a very good limb. He wears an Arnold's knee apparatus and is able to follow his usual employment of a slate miner without any inconvenience to the present date (Jan. 15th, 1900).

Remarks by DR. MILLS-ROBERTS —The patient on admission was emaciated and badly nourished. He had been for years a sufferer from chronic dyspepsia and had a bad tuberculous family history. His temperature during the time that he was in hospital ranged from 99 4° to 99·8° F. with one exception. On May 28th he complained of severe pain in his side. The morning temperature was 102 8° and the evening temperature was 103 4°. His breathing during the whole of this day until about 5 A.M. on the 29th had a distinct Cheyne-Stokes character. On the night of the 28th he had severe diaphoresis. By 8 A M. on the 28th his breathing had become normal and the pain had disappeared. This condition was in all probability due to the injuries his body had received from the different falls of débris. Taking his tuberculous history into account I felt greatly tempted to give him a stiff knee, but the inflammatory condition of the knee was so amenable to treatment that I decided to try passive movements and massage and to give him a moveable knee.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Primary Resection of Gangrenous Intestine.—Primary Abdominal Section for Wounds of the Abdomen.

A MEETING of this society was held on Jan. 26th, Sir R. DOUGLAS POWELL, Bart, the President, being in the chair.

The PRESIDENT referred in graceful terms to the loss which the society had sustained by the death of Sir James Paget who had been not only an honorary member of the society but was the first surgeon to occupy the presidential chair.

Mr. JONATHAN HUTCHINSON, jun, read a paper on Resection of Gangrenous Intestine in Cases of Hernia based on a comparison of 42 cases. He related two cases of successful primary resection of small intestine during herniotomy, both operations being performed by simple enterorraphy without mechanical aids. One case was that of a woman with a strangulated femoral hernia on whom he had operated in 1893, removing five inches of damaged gut; she was in good health six years later. The second case was that of a man with strangulated inguinal hernia in which it was necessary to excise ten inches of intestine; this was done by Maunsell's method—that is, one in which an artificial intussusception was made. The patient made a perfect recovery, but died three years later from ulcerative colitis, and the specimen was fortunately obtained for Mr. Hutchinson by Mr. H. L. Barnard. It was shown at the meeting and proved that there had not been the slightest narrowing at the site of the resection. Mr. Hutchinson remarked that it was probably the general impression that the use of Murphy's button had rendered resection of intestine not only quicker but safer. To test this belief he had collected from hospital records (including all the cases he had himself operated on both with and without this apparatus) 15 examples of primary resection for gangrenous gut performed with Murphy's button and 16 cases in which suturing alone was employed. Of the former only one (7 per cent.) had recovered and of the latter six (37 per cent.). 11 cases treated by conservative measures (e g., formation of an artificial anus) without resection had all died. None of these cases were included in Dr. Kendal Franks's paper published in 1893, and they were not selected in any way excepting that they had all been under the care of hospital surgeons. This was a very striking comparison, but besides this the fatal cases treated by suturing alone had lived on an average twice as long as those in which Murphy's button had been used; in other words, they had given much more promise of survival. Three out of the 10 fatal cases of simple suturing would probably have recovered but for accidental complications (multiple strictures of small intestine, obstruction of intestine by an omental band, and tuberculous phthisis causing constant cough). Moreover, the post-mortem records showed, on the whole, better union of the divided ends after suturing than after the use of Murphy's button. The latter was apt to cause acute congestion by its bulk; its weight was also a disadvantage, and even should the patient recover it was probable that a stricture might result. At any rate, the openings made by operations with Murphy's button in gastro-jejunostomy sometimes showed a marked tendency to contract. The greater time required for the accurate performance of suturing did not appear to be of much practical importance—it had probably been a little exaggerated. The after-shock had not been dangerous in his experience. Whilst primary resection of gangrenous, perforated, or irretrievably damaged intestine in a hernia must always be attended with high mortality, yet it offered the best chance of recovery. This agreed with the results previously brought forward by Dr. Kendal Franks, Mr. C. B. Lockwood, and other surgeons. Turning to the details of the operation in performing resection it was of great importance to excise enough of the damaged intestine so that the sutures might be placed in healthy tissue, and it was nearly always advisable to do it through a median abdominal wound. Special care had to be taken with the mesenteric edges of the two ends, for leakage most readily occurred at this point. Maunsell's method was probably one of the best to employ. If the intestine could be emptied and made to contract this would favour sound union and tend to prevent infection of the stitch apertures by the septic contents. It was probable that the administration of an aperient immediately after the operation would lead to better results than in the past. Mr. Hutchinson had operated on 140 cases of strangulated hernia with a total mortality of 25 per cent. 65 were inguinal hernia, of which 54 recovered; 54 were femoral, and of these 40 recovered; whilst 21 were umbilical, and of these 12 recovered, 34 deaths in all. The great majority were due to the gangrenous or acutely inflamed condition of the intestine and omentum at the time of operation. Five of the fatal cases were possibly due to the employment of too conservative methods.—Mr. ARTHUR BARKER remarked that the question of how to deal with the intestine during operation was a very important one. He did not think that Mr. Hutchinson had resected the gut too lavishly. He quite agreed that primary resection was preferable to Murphy's button. He mentioned a case in which the weight of the button had dragged the paralysed bowel down into the pelvis and caused death. He had given it a very fair trial and had had considerable success with it, but there was no better method than the simple suture. As to the question of time occupied in suturing as compared with the use of the button, that depended very much on the operator The condition of the intestine was the key to the position and it was of the greatest importance to remove sufficient and suture healthy tissues to healthy intestine beyond the strangulation. In one case he had removed 35 inches of the gut and the case had made a perfect recovery. Out of 11 "anastomosis" operations which he had recently performed he had used the Murphy's button on three occasions. Two of these 11 were gastro-enterectomies in both of which the button was used and both recovered; two were pylorectomies, both were sutured, one recovered and one died; three were resections for gangrenous intestine, one with the button died and two with suture recovered. Three were lateral anastomosis operations, all with suture, and all three recovered; one was a case of excision of the *cæcum* in which the suture was used and this recovered. Thus, out of eight cases in which a simple suture was used one died, and out of three in which the button was used one died, results which supported the method of simply suturing the bowel.—Mr. HOWARD MARSH referred to the great difficulty in deciding as to the true condition of a piece of intestine. It was often impossible to say if the intestine would recover or not. The bowel was often completely paralysed and obstruction resulted from this. On the whole, it was better to excise the piece of gut if in doubt. Resection was not nearly such a dangerous procedure as was formerly believed. It was most important, he thought, to remove it freely, and he quoted cases in illustration. He had no doubt that the continuous suture was better than Murphy's button. He congratulated Mr. Hutchinson on the excellent results that he had achieved which were a distinct advance on previous statistics.—Mr. CHARTERS J SYMONDS hoped they should save many more lives by modern methods and by dealing more boldly with the intestine. He referred to the difficulty of emptying the intestine at the time of the operation. This was very important, for in this way it was possible to prevent symptoms of paralysis of the bowel. He quite agreed with the advantages claimed for the direct suture as compared with the use of the button —Mr HUTCHINSON, in reply, said that he had used interrupted sutures of fine silk passed through all the tissues of the intestinal wall. The sutures became absorbed or at any rate disappeared. He wished to draw attention to the fact that in the specimen exhibited there-were no adhesions around the bit of intestine and the serous surface was perfectly smooth. This patient had died from ulcerative colitis, wholly unconnected with the illness for which the operation had been performed some years before. He wished to refer to the advantage of sewing up the abdominal wound layer by layer. He quite agreed with the importance of emptying the bowel at the time of the operation and he saw no harm in the use of a mild aperient afterwards. In gastro-jejunostomy he had been equally impressed with the advantage of direct suture.

Mr. A. **PEARCE GOULD** read a paper on a case of Bullet Wound of the Abdomen, with four wounds of the small Intestine and two of the Mesentery; Operation; Recovery: The patient was a young man, aged 20 years, who was accidentally shot with a small revolver on the evening of Oct. 30th, 1899. A medical man, who was called to him found him in great pain and at once administered a hypodermic injection of morphia, and then took him to the Middlesex Hospital where he was seen by Mr. Pearce Gould about an hour after the accident. The wound in the abdomen was two inches below the navel and one inch to the left of the middle line. There was still some pain, the respiration was easy, the abdomen moved freely, and the pulse was 96. The liver dulness was not obliterated and there was no dulness in either flank. There was no paralysis. Six ounces of clear normal urine were drawn off by catheter. Under an anæsthetic the wound was explored and was found to extend into the peritoneal cavity. This was freely opened and blood flowed out from it, but neither gas nor intestinal contents were observed. The intestine was examined and four wounds were found; three of these were apparently in the jejunum perforating and the other involved the serous and muscular coats only. There was no visible escape of intestinal matter. These wounds were closed with Halsted's sutures of sterilised silk and two wounds of the mesentery which were close by were also sutured. No other lesion was found. The peritoneal cavity was cleansed, the bowel was returned, and the abdominal wound was closed. The man made an uninterrupted recovery and left the hospital well on Dec. 4th. The bullet was found lying deep in the left buttock and was allowed to remain. In commenting on this case Mr. Pearce Gould drew attention to the following points: (1) the multiple lesions produced by a single bullet; (2) the absence of serious symptoms; and (3) the necessity for exploration, even in spite of the absence of all symptoms, to determine whether the wound was perforative, whether any viscus or large vessel was injured, and, if so, to treat them. He emphasised the importance of the hypodermic injection of morphia immediately after the accident, both in relieving pain and shock and in controlling the movements of the intestine, and so lessening the chance of fouling of the peritoneum with germ-laden intestinal contents. The case illustrated the necessity for careful and thorough exploration of the abdomen (by operation) in all cases of perforating wound and severe contusion of the abdominal wall.—The **PRESIDENT**, referring to the use of opium in abdominal injuries and wounds, said that although it had been discarded, not without reason in these cases, it was one thing to give it before diagnosis and another to give it after the diagnosis was made. The morphia syringe might be of great use on the battle field. When gangrene of the intestine had been diagnosed there might be no harm in giving morphia. As to the absence of symptoms in Mr. Gould's case this was possibly due to the narcotism of morphia.—Mr. **ARTHUR BARKER** remarked that there was no more difficult class of case to deal with than that narrated. The amount of shock in such cases varied very considerably, and he mentioned the case of a patient shot through the abdomen who walked downstairs and professed himself as feeling quite well. In another case with the same kind of wound there had been great shock. As to the procedure adopted that must vary with the time which had elapsed since injury. If seen early the abdomen should be searched, but if not seen till later it might be well to wait. The velocity of the bullet was another factor. If the speed was great then the intestinal wounds would be very small. In general an operation might well be undertaken in any doubtful case. He quite agreed with the remarks made on the value of opium.—Mr. **HOWARD MARSH** referred to the possible absence of symptoms even with very grave internal lesions and mentioned a case in point of ruptured colon. In another case of injury in the hunting field the patient went to the city and was well for two days. Then he passed into a state of shock and died. The necropsy revealed rupture of the super-mesenteric artery as a consequence of which part of the small intestine had become gangrenous. He certainly thought it well to operate more freely. An exploratory operation was not attended with much risk. He believed in saline injections as a most valuable method for the treatment of shock.—Dr. **NEWTON PITT** referred to the remarkable way in which a "cow-doctor" would puncture a distended intestine with a large trocar. He inferred from this that small bullets with high velocity would not do great damage to the intestine.—Mr. **PEARCE GOULD**, in reply, said that the patient was not narcotised but he was only relieved from pain by the morphia. The amount of shock in such cases seemed to depend very much on the parts which were damaged. If the great sympathetic plexuses were injured then probably there would be great shock. In his case the shock at the end of operation was not great enough to call for saline injection. His main object in bringing forward this case was to emphasise the importance of operation in all perforating injuries of the abdomen.

OPHTHALMOLOGICAL SOCIETY.

Experimental Exophthalmos and Enophthalmos.—Cicatrix Horn growing from the Cornea.—Glaucoma following the use of Homatropine.—Exhibition of Cases and Card Specimens.

AN ordinary meeting of this society was held on Jan. 25th, Mr. G. **ANDERSON CRITCHETT**, being in the chair.

Dr. **WALTER EDMUNDS** read a paper on Experimental Exophthalmos and Enophthalmos in which he remarked that there were three ways in which prominence of the eyes could be affected experimentally: (1) by acting on the sympathetic, either stimulating it or dividing it; (2) by the administration of certain preparations or drugs; and (3) by operations conducted on the thyroid gland. With regard to the first, stimulation of the cervical sympathetic produced: (1) prominence of the eye; (2) widening of the palpebral fissure; (3) at first increase and later decrease of the intra-ocular tension; and (4) erection of the hairs of the head. Division of the sympathetic produced the opposite effect. Cocaine was one of those drugs which produced proptosis, widening of the palpebral fissure, dilatation of the pupil, and decrease in the intraocular tension. Cunningham had shown that feeding a healthy animal on thyroid extract produced similar results. Dr. Edmunds then showed photographs of monkeys and rabbits both before and after feeding on this substance. Exophthalmos after the administration of thyroid had once been observed in man by Beclère, where it appeared after excessive doses had accidentally been taken by a patient suffering from myxœdema. The third method of effecting the prominence of the eyes was by operations on the thyroid. Removal of the thyroid might produce either exophthalmos or enophthalmos, but in the monkey usually the latter. Numerous lantern slides were shown of animals in which this had been done, as well as drawings of animals in which the sympathetic had been divided. Dr. Edmunds summed up his results by saying that the discussion of these phenomena was particularly interesting in its bearing on the pathology and treatment of Graves's disease; the fact that the most important eye symptom of Graves's disease could be produced by the administration of thyroid preparations certainly suggested that the eye affection was secondary to the goitre. He had not tried the effect of division of the sympathetic in feeding with thyroid extract, but with the administration of cocaine it diminished the effect produced. It therefore suggested itself that the exophthalmos might be benefited by division of the cervical sympathetic, and, indeed, the operation had been tried several times in man. The results were said, however, not to be very satisfactory, at least as far as the general disease was concerned.—Mr. J. B. **LAWFORD** referred to a case reported by him in which exophthalmos had resulted from thyroid-feeding in a woman, aged 34 years, who had suffered from myxœdema for five years. She was treated with the extract with great benefit; but relapsing four and a half years later the treatment was resumed, this time with the development of severe exophthalmos. Her subsequent history was unknown.—Mr. G. **MACKAY** described a case in which exophthalmos followed an operation on the cervical glands in which the sympathetic had evidently been divided. He also quoted a case of extreme exophthalmos benefited by the removal of half the thyroid gland.—Mr. W. H. H. JESSOP cited a case in which death followed division of the sympathetic.—Mr. H. E. JULER stated that he had seen in Paris a case of glaucoma in which division of the sympathetic had produced many unpleasant symptoms without enophthalmos.—Dr. W. A. BRAILEY also spoke on the subject and Dr. EDMUNDS replied.

Dr. ARNOLD LAWSON read a paper on a case of a Cicatrix Horn growing from the Cornea. He said that a careful search through ophthalmological literature had failed to discover another example of this curious condition. The patient was a female child, aged eight years, a hydrocephalic idiot. The history given was that about one year previously a white spot had appeared on the right eye and that the eye began to project. Six months later a growth was first noticed on the right cornea and this had constantly increased in size. Latterly a white spot had appeared on the left eye. On examination of the eyes there was seen a large conical tuberculated excrescence protruding between the lids of the right eye. It was half an inch in length and its base attached to the cornea covered about four-fifths of its surface. The left cornea exhibited a yellowish infiltration just below the pupil over which the cornea was bulging; the anterior chamber was deep, the iris was immobile, the tension was slightly raised, and the eye was quite blind. Both globes were very anæsthetic and there was considerable muco-purulent discharge from a chronic inflammation of both conjunctival sacs. The growth upon the right eye was accidentally detached a few days after admission into the hospital and it was then seen to have been attached to the cornea at the apex of a central staphyloma which was left covered by a fleshy soft core which had formerly been embodied in the centre of the growth. The cornea was entirely opaque and the eye was quite blind. After removal of the right eye a few days later examination of the globe revealed a co-arct retina with evidences of chronic degenerative changes in all the various structures. The anterior chamber was completely abolished, the iris throughout its extent being firmly adherent to the back of the cornea, which was bulging centrally. The apex of the corneal staphyloma had evidently been the site of a large perforation which was closed by the fleshy granulations which formed the core of the growth. The growth itself measured half an inch from apex to base and one and a half inches round its base. The interior portion was soft and crumbling, but the external layers were hard and horny and cut with difficulty. A wedge-shaped piece was cut away from the growth and specimens were cut and stained with carmine. The microscope showed that the external layers consisted of several faintly fibrillated strata of a dense homogeneous nature. The layers occupied about one-quarter of the entire thickness of the walls, the rest being entirely composed of small nucleated cells, those most external being stratified. Adopting Mr. Bland Sutton's classification of human horns, this growth would be an example of a cicatrix horn, the rarest of all varieties of horn, and one which had been usually found in connexion with the cicatrices of burns and scalds. The probable etiology in this case was an overgrowth of granulation tissue closing the perforation in the cornea, which, owing to an unhealthy condition of the wound and eye, which was anæsthetic and atrophic, had become exuberant, simulating exactly the condition known as "proud flesh" elsewhere. By a process of accumulation and heaping up the granulations gradually formed a cap over the cornea, whilst the external layers gradually became stratified and horny from the pressure of fresh growth from the central core and by the action of the air. The nature of the growth was evidence that the corneal epithelium bore no share in its production and discounted the possibility that it might be due to a huge crust of inspissated conjunctival discharges.—Remarks were made by Mr. TREACHER COLLINS and Mr. DEVEREUX MARSHALL.

Mr. C. H. B SHEARS read notes of a case of Acute Glaucoma following a Single Application of Homatropine. A woman, aged 52 years, went to the Liverpool Eye and Ear Infirmary in October, 1899, for reading-glasses. With her hypermetropia corrected her distant vision was nearly two-thirds of normal. One or two drops of homatropine, four grains to the ounce, were put into the right eye. When she came again to the hospital a week later she had all the signs of acute glaucoma in this eye and she could only just count fingers. Pain and vomiting and great loss of sight came on the same evening that the homatropine was used. Eserine and leeches were tried for two hours but without benefit. Iridectomy was then performed, with the result that the tension and sight were quite restored in ten days and had remained satisfactory up to the present. Mr. Shears was of opinion that no mydriatic should be put into the eyes of persons over 30 years of age without careful consideration; that if homatropine were used it would be well to instil eserine before the patient left the hospital; that cocaine followed by eserine was usually quite sufficient for ophthalmoscopic examination; or the new pupil dilator—euphthalmine—would be found very satisfactory for this purpose. Very few cases were published of glaucoma after homatropine and the accident appeared to be very rare.

The following cases and card specimens were shown:—

Dr. E. E. HENDERSON: Microscopic Sections of Growth from the Upper Palpebral Conjunctiva.

Mr. A. Q. SILCOCK: Persistent Hyaloid Artery arising from a Central Coloboma of the Choroid.

Mr. W. T. HOLMES SPICER: (1) Detachment of the Choroid; and (2) Primary Optic Atrophy associated with Diabetes Insipidus.

Mr. L. V. CARGILL: Fibromata in the Eyelids.

Mr. R. W. DOYNE: (1) Peculiar Appearance in the Cornea; (2) Extreme Cases of Essential Shrinking of the Conjunctiva; and (3) Unusual Case of Striated Keratitis.

Dr. G. F. STILL: Infantile Cerebral Degeneration with Symmetrical Changes in the Macula

Mr. H. E. JULER: A case of Pemphigus of the Conjunctiva.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The Application of Bacteriology to Public Health.

A MEETING of this society was held on Jan. 12th, Dr. A. NEWSHOLME, the President, being in the chair.

Mr. WALTER PAKES read a paper on the Application of Bacteriology to Public Health. This, he said, had already resolved itself into two branches, the pathological and the technical, each demanding long study and practice; indeed, there was no department of research in which a little knowledge was so dangerous a thing or so prone to lead to the grossest errors. He felt this very strongly in connexion with the bacteriological examination of water, milk, and even of pathological secretions by the public analysts, who, though rightly required to be highly qualified chemists, if not Fellows or Associates of the Institute of Chemistry, are not required to have the knowledge and training essential to the exercise of functions which, if not committed to professed bacteriologists, should be jealously retained by the medical officer of health This officer if he had undergone a course of laboratory instruction, might easily become an adept in the examinations required for purposes of public health. These examinations were—(1) diagnostic and (2) preventive. Perhaps the most important of the former was the identification of the tubercle bacillus in milk, the more so since it appeared to acquire greater virulence in the bovine organism, and infants were far more susceptible than adults. With proper precautions as to the complete decolourising of the tissues or the milk residue, it could be identified with certainty and distinguished even from the smegma bacillus which most nearly resembled it both in appearance and in its behaviour towards stains, and had been found in the sputa, urine, and milk. Mr. Pakes described the precautions to be observed in taking samples of these secretions and of fæces, and the details of a modification of the Ziehl-Nielsen and Honsell's staining processes. Next in importance was the diagnosis of diphtheria. He had examined the secretions from nearly 3000 sore throats, of which 1836 during the last five years had been systematically examined for the different microbes, with results which he exhibited in tabular form. The Klebs-Löffler had been found alone in 289 and associated with Hoffmann's in 18, and with strepto- or staphylo-cocci in 36, making 343 of true diphtheria, Hoffmann's alone in 89 and with cocci in 10, strepto- or staphylo cocci or both in 339, while the rest showed other forms or none. Hoffmann's gave rise to an infectious and specific sore-throat, and the so-called "septic throats" were caused by streptococci, differing morphologically from those present in health, and by staphylococci, especially staphylococcus aureus, which as well as the saccharomyces albicans produced a membranous exudation indistinguishable clinically from that of true diphtheria. He gave examples of the value of bacteriological examination in verifying and in correcting clinical diagnosis, whether positive or negative, and explained the circumstances under which the Klebs-Löffler bacillus, though present in the throat, might fail to appear in the cultures. He believed that whatever the cost of the bacteriological examination of every "sore throat" among school children, it would, as a means of preventing outbreaks of diphtheria, effect a saving of public expenditure as well as of lives. More difficult was the detection of the Eberth-Gaffky or typhoid bacillus; to look for it in the blood was useless and in the urine it appeared far too late for diagnostic purposes. It was present in the spleen and Peyer's glands from the first, but these were inaccessible. In the fæces it might be found late in the second week, but only when set free by ulceration, and then its isolation from the bacillus coli communis was beset with difficulties as yet well-nigh insuperable. In all cases in which the diagnosis during life had been doubtful the splenic pulp should as soon as possible after death be examined by cultures and by the so-called Widal's test. He felt it a duty he owed to his master, Gruber, to state that the credit of the discovery of this test was really due to him, that he had suggested its employment in the diagnosis of enteric fever and cholera, whereas all that Widal did was to diagnose enteric fever during life by the application of Gruber's reaction. Mr. Pakes then described at considerable length the procedure as practised at Guy's Hospital, the cultures, dilutions of the serum to various degrees, and the conclusions to be drawn from the occurrence or absence of a reaction with each at successive stages in the course of the disease. One remarkable observation was that there were cases of undoubted enteric fever in which the organism made no attempt to combat the disease, and for that very reason the patient's serum failed to react. With these rare exceptions Gruber's test was almost conclusive even when opposed to the clinical diagnosis, for with the precaution of successive observations the error due to the patient having been immunised by a previous attack might be avoided. Preventive examinations were quantitative or qualitative. In the quantitative examination of water, which was essentially a comparative observation, it was of the utmost importance that all the conditions of collection, media, inoculation and plating, temperature and periods of incubation, and the mode of enumeration should be identical. These he explained at great length, indicating at each step the most frequent causes of discrepancies and errors, some of which had received little if any attention. Thus in very foul waters insufficient dilution led to almost incredible under-estimation of the numbers of the bacteria, the stronger colonies saturating the gelatin around with toxins fatal to other and weaker forms in their vicinity. Thus, having made two dilutions of a sewage effluent of 1 in 10 and 1 in 1000 respectively the means of several plate cultures of each gave estimates of 386,000 and 4,600,000 to the cubic centimetre, or nearly 12 times as many in the case where there had been a hundredfold dilution. The sample should be packed in ice until the incubation had begun and the enumeration made on the third day, the temperature giving the most valuable results being 20° C. Pathogenic germs, however, grew best at 37° C, the temperature of the blood, but they and others flourishing at the same temperature were usually as 1 to 10, 15 or 20 of those thriving at 20° C., and relatively less numerous as the total numbers were greater. Discussing the qualitative examination he referred to the inadequacy of most descriptions of bacteria for their identification and enumerated the points that he felt requisite for a complete definition. The organism that in this country was most desired to identify in water was that of typhoid fever, but this was very rarely possible, it being necessarily associated with numerous intestinal bacteria, especially the bacillus coli communis, which was not only far more numerous and stronger, but yielded a toxin extremely fatal to that of enteric fever. None of the procedures hitherto adopted for their separation were satisfactory. He then explained his own method based on the facts that practically none but the Eberth-Gaffky, the bacillus coli, and the bacillus enteritidis of Gaertner would grow at 42° C. and anaerobically. He used Kitasato's glucose formate broth and Buchner's tubes incubated at 42° C. for 24, 48, and 72 hours, transplanting any growths to Petri's dishes at 20° C. The water to be examined he concentrated to $\frac{1}{100}$th of its volume by filtration through a "bougie" from within outwards under a pressure of three atmospheres. He thus found in the 300 samples of water examined 50 per cent. of them to contain bacillus coli. The quantity of water operated upon varied from 200 cubic centimetres to as little as 20 cubic centimetres, the smallest volume of the same waters yielding colonies under the carbolic process having been at least 600 cubic centimetres. It was futile to look for, or at any rate to rely on, the possible but improbable detection of the typhoid bacillus, but the bacillus coli was synonymous with sewage, although almost ubiquitous. For practical purposes water containing it in 20 cubic centimetres or less should be condemned, in quantities between 20 and 50 cubic centimetres deemed highly, and in those between 50 and 100 cubic centimetres slightly, suspicious. Only when still larger volumes were required could a water be pronounced probably safe, or if none could be found in the two litres used absolutely so. He would not depreciate chemical analysis, but if bacteriology could not demonstrate previous contamination by organic matter, long since completely transformed into nitrates, chemistry could not differentiate between infective and inert organic matter, or even between sewage and vegetable matter. He had found the bacillus coli in every five cubic centimetres of a water which yielded only 0 004 part of albuminoid ammonia and used up only 0 02 part of oxygen per 100,000, in which when on a previous occasion these figures had been 0·003 and 0 01 respectively there were no bacilli coli found when 50 cubic centimetres of water were examined. The examination of milk was attended by special difficulties; the bacteria varied under circumstances from a few scores, hundreds, or thousands to 30,000,000 per cubic centimetre, London milk usually containing from 3,000,000 to 4,000,000. It therefore required dilutions from 1 in 10 to 1 in 1000, as did sewage. Then as a product of the living body it was very apt to contain organisms like the streptococci thriving at 37° C, but easily crowded out at 20° C, while for sterilising he found neither Pasteurising at 65° C. nor exposure to 100° C for ten minutes sufficient, undiluted milk requiring half an hour's boiling, and milk with an equal volume of water a like exposure to a temperature of 80° C. Centrifugalisation of the milk in stoppered tubes was indispensable, and the cream and the sediment should be spread separately on cover-slips, dried, flamed, stained, and examined, the removal of every trace of fat being imperative, especially in the application of the Ziehl-Nielsen process for the detection of tubercle bacilli. Failure to demonstrate these, certainly in the case of mixed dairy milks, had no more value than other negative evidence. The streptococcus of bovine mastitis was often found, of course accompanied by numerous pus cells and leucocytes; and though a few leucocytes were always present and the streptococcus had not been certainly proved to be pathogenic to man, yet milk the product of an inflamed udder, the sediment from which had been taken by a pathologist for pus from a psoas abscess, was not fit for human, much less for infants', food. He would put the limit at a dozen or so leucocytes in the field of a one-sixth objective. Inoculation experiments on guinea-pigs were always desirable in doubtful or negative cases, but the sediment used should first be submitted to a temperature of 56° C. for 10 minutes by which means certain organisms often present and speedily fatal to guinea-pigs were rendered innocuous. The bacilli of enteric fever and of diphtheria might be introduced from without; the latter might be detected in cultures on inspissated blood serum, but the search for the Eberth-Gaffky was even more hopeless in milk than in water, while the bacillus coli was almost always present. He concluded with a few remarks on ice creams, the examination of which was the same as that of milk, though the enormous numbers of the bacteria made extreme dilution imperative. But though from 20,000,000 to 30,000,000 might be present the effect of boiling the milk, often done to prevent souring, must not be forgotten. He had himself with no other precaution than this made from milk containing 4,000,000 bacteria per cubic centimetre ice creams with only 1000. One can thus understand how by boiling the milk, &c., ice creams prepared amidst the least cleanly surroundings may be made to contain the fewest bacteria.

CLINICAL SOCIETY OF MANCHESTER.

The Prevention of Tuberculosis.

A MEETING of this society was held on Jan. 16th, Dr. JUDSON S. BURY, the President, being in the chair.

Dr. JAMES NIVEN, medical officer of health of the city of Manchester, opened a discussion on the Prevention of Tuberculosis. He remarked that a great reduction had taken place in the mortality ascribed to phthisis during the last 50 years, especially in the earlier decades of life. This had been ascribed to what might be called indirect methods of prevention, such as improved conditions of dwelling, the drainage of the soil, an improved standard of cleanliness, the diminution of overcrowding, improved ventilation, the lighting and cleansing of workshops, and the diminution of the hours of work. To these factors might be added others certainly no less important, such as the abolition of child labour, contrivances for the removal of injurious dusts, better and cheaper food, and cheaper clothing. Some of these were precarious in their tenure and, unfortunately, they were amongst the most important—viz., the possession of better and cheaper food, cheaper clothing, and the diminution of overcrowding. Another set of indirect conditions making for betterment were those pertaining to the knowledge of disease and especially to a knowledge of this disease. The pathology of tuberculosis was, thanks to the discoveries of Villemin, Chauveau, Koch, and others, now so much better understood than was previously the case, and the conditions under which the disease was held in check were so much more fully appreciated, that the proportion of complete recoveries was steadily improving. Moreover, cases treated by a skilful physician or surgeon would now under his instruction cease to be a source of infection. Although they might confidently expect the influences just enumerated to continue to exercise an effect on phthisical mortality, that influence would be limited and there would be always counteracting forces at work tending to the production of overcrowding, alcoholism, and dirt—each of them potent factors in maintaining the disease. It was certain that the indirect means of prevention were inadequate to reduce tuberculosis to a negligible quantity. Could they do better by direct means of prevention? The answer was that they could, and that in any case they were bound to use their knowledge of known dangers to remove them. The all-essential condition in the direct campaign against tuberculosis was an educated, rigorous cleanliness. By the side of this condition others fell so completely into the background that they might for their present purpose neglect them. This educated cleanliness implied two sets of operations: (1) those directed against allowing sputum (or other infective discharges) from phthisical or bronchitic persons to be dried and broken into dust; and (2) those directed towards preventing the possible accumulation of such dust should the direct interception of discharges fail through ignorance or inadvertence. How, then, were they to pervade all ranks of society with a working belief in the necessity and efficacy of such measures, and in particular to bring them home to tuberculous people and their relatives? For this purpose they might be said to have three main forces. Of these probably the most powerful was the medical profession. No medical man should now be allowed to leave any medical school or to pass his final examination without a working knowledge of the measures by which he was obliged to counteract the propagation of tuberculosis from any person who might consult him. The drilling required for the purpose was little compared with the advantage to be reaped. Then, again, the sooner the nature of an attack was perceived, the sooner would effectual measures of prevention be taken. Hence every medical practitioner should know how to examine discharges for tubercle bacilli and he should also know how to diagnose obscure illnesses by the use of minimal doses of tuberculin It would, no doubt, usually happen, especially in difficult cases, that busy practitioners would refer such examinations to a bacteriological expert in the former case and to hospital physicians in the other But the knowledge would be both useful and valuable all the same. It was necessary to recognise at the same time that busy practitioners in the poorest quarters of large towns would not have the time to give the instruction required, much less to see that it was carried out. It was in the poorer districts, then, that the work of prevention which they were entitled to expect from practitioners would absolutely need much supplementing. In fact, the work in such districts would have to be done by other agencies. It was at this point that their second force came in—viz., the sanitary authority. The work of the sanitary authority was chiefly concerned with instruction and cleansing. The work of instruction had been carried on by the Manchester Corporation on a tolerably large scale. In three different years handbills had been distributed to every house in the city giving instructions in the precautions to be taken in the presence of phthisis. The Ladies' Health Society had also given a great amount of instruction in the poorer districts. A great work of education had been carried on by the medical staff of the Manchester Hospital for Consumption for many years, aided by leaflets prepared by Dr. Ransome. Not a few popular lectures had been given and the subject had been of late frequently mentioned in the newspapers. There was no doubt that the general public was beginning to know more about it and to take precautions, although this would not apply to the poorest class. Young medical men ought to instruct the people by suitable lectures, which would render their own ideas precise and do much good. The sanitary authority was extending its sphere of instruction. Voluntary notification of phthisis had now been in force in Manchester for four months and Dr. Harold Coates was carrying out the administration which had ensued. In order to establish their methods and to advance with a sure foot they had requested notifications, so far from public institutions only. During the four months they had had some 450 notifications. In each case reported, Dr. Coates visited the house and saw that the requisite measures of disinfection were carried out, gave precautionary instructions, and investigated the etiology of the case when possible. Generally disinfection was carried out in their usual manner. When the patient could not be shifted from his room the bedclothes were all changed, and the bedclothes, &c., disinfected with steam as usual, the room was disinfected with solution of lime, and not with solution of chloride of lime. Fortnightly visits were generally paid by the visitors of the Ladies' Health Society, who saw that strict cleanliness was kept up In this way the rooms were rendered free from infection; all that was subsequently necessary was, not successive disinfections, but a sustained cleanliness. It would be noted also, that, so far, they had completely surmounted the objection to notification, but that it would be impossible to keep such precautions up. There had been no real difficulty, nor did he anticipate any if the present organisation were extended. Not only so, but what had really surprised him was that, with, he thought, one exception, the agents of house property had readily acceded to his request that they should agree to the disinfection of the house or of particular rooms. As they had to repaper and sometimes to repair the rooms disinfected the expense entailed was not inconsiderable. In the instance in which exception was taken an explanation was found sufficient to remove all objection. The third force at their disposal was treatment in hospital. The difficulties in the way of this resource lay in the great expense which it would involve. A sanatorium for consumptives was of great value in the way of educating patients in the means and habits of personal prevention. What was even more wanted for direct prevention was an isolation hospital which would receive not early cases, but patients in a more advanced stage. Patients who were bedridden had, naturally, a considerable objection to go to any home for dying cases, although they went, but very reluctantly. It would be an excellent thing if, with the sanatorium about to be provided for the treatment of tuberculous patients from Manchester, there could be combined at the public expense an isolation hospital in the same grounds. There would then be no difficulty in getting suitable cases admitted. These would be selected as the result of notification from among those households in which the greatest benefit in the way of prevention could be conferred. There was now a strong feeling growing up, largely in consequence of the action taken at Liverpool, that the guardians of the poor should make suitable provision for tuberculous patients. Such provision would necessarily be largely in the nature of isolation blocks, but might usefully be sub-divided into a sanatorium and an isolation hospital. If this movement extended it was to be hoped that there would be no idea of pauperisation attached to the tuberculous poor, so that the benefit of these institutions might be extended to those who had not sought relief. Meanwhile, it was to be hoped that a full response would be made by the medical profession to the request of the corporation for a notification of cases, so that they might know what hospital provision would be required and on what shoulders it might best fall. This was, of course, only one of the results of notification, but it might prove to be one of great importance. He would again repeat that in the interests of prevention hospital provision for consumptives would, in his opinion, most usefully take the shape of a joint sanatorium and isolation hospital.

A vote of thanks was given to Dr. NIVEN and the following gentlemen took part in the discussion: the PRESIDENT, Dr. T. C. RAILTON, Dr. H. R. HUTTON, Dr. A. WAHLTUCH, Dr. T. HARRIS, Professor W. J. SINCLAIR, and Dr. E. VIPONT BROWN.

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases and Specimens.—Treatment of Mastoid Abscess and the Radical Cure of Suppurative Otitis Media in Children.

THE fifth ordinary meeting of this society was held on Jan. 17th at the Medical Institute, Birmingham, Dr. E. RICKARDS, the President, being in the chair. The following gentlemen were elected members of the society: Dr. W. D'Este Emery and Dr. W. R. McCamon.

Mr. H. G. BARLING showed a patient who had suffered from Chronic Intestinal Obstruction which he had relieved by the formation of a fæcal fistula and subsequent intestinal anastomosis. The patient was a male, aged 52 years, and for 15 months had suffered from attacks of abdominal pain of great severity. During the last four months before he came under observation he had suffered much from constipation and his abdomen had during this time increased steadily in size whilst he had lost in weight; later he only passed flatus per rectum and no motion at all. Finally, there was no escape of flatus. The abdomen at this time (Oct. 24th, 1899) was extremely and generally distended and was very tense, no tumour could be palpated, and there was nothing in the rectum. Vomiting was entirely absent and had been so all along; the pulse was about 90 and the temperature was 100° F. As it seemed probable that the sigmoid flexure was distended an opening was made with the intention of performing sigmoid colotomy, but this part of the bowel was found to be empty, as was the small intestine. The finger in the wound detected a huge coil of distended bowel towards the middle line of the abdomen, but this could not be brought into the wound. This incision was therefore closed and another was made between the middle line and the first incision, exposing the distended coil of gut, and to it by a complete circle of sutures the peritoneum and transversalis fascia were secured. A small opening was now made into the gut and a huge fæcal escape took place for days. On Nov. 10th the abdomen was opened in the middle line below the umbilicus and the cause of the obstruction sought. It was found to exist in the large intestine just below the splenic flexure; the exact nature of the obstruction could not even then be determined, but there was extreme narrowing of the bowel for about three inches in length, and the intestine was firmly bound down to the posterior abdominal wall and there were some enlarged glands in the meso-colon. The piece of intestine which had been opened proved to be the transverse colon which had made a V-shaped bend downwards towards the pelvis. An anastomosis was made between the transverse colon and the sigmoid flexure with the largest sized Murphy button. A very good recovery followed and in a few days the fæcal fistula had healed. The patient was passing a satisfactorily formed motion every day and had gained weight to the extent of ten pounds. The button was still retained. The patient was shown to illustrate how complete a barrier the ileo-cæcal valve formed, preventing any regular regurgitation from the distended large intestine into the small, and as an example of the advantage during the period of obstruction in chronic cases of simply giving relief by fæcal fistula, leaving more radical treatment to a later period when the obstruction had been thoroughly removed.

Dr. O. J. KAUFFMANN showed a man, aged 33 years, suffering from Scleroderma. The patient had been exhibited to the society on Oct. 11th, 1899, and was now again shown because the sclerotic condition was improving markedly in the thigh, whilst in the leg it appeared to be at a standstill. Some doubtful fresh patches had meanwhile appeared in the neck. The general health had remained perfectly good.

Mr. J. FURNEAUX JORDAN showed two specimens of Uterine Myoma. The first specimen was an interstitial *myoma of about the size of a* Tangerine orange It had been removed by vaginal hysterectomy in August last from a woman, aged 51 years. The menopause had taken place three years previously, but although there had been no hæmorrhage the uterus had given her more and more trouble. It had become retroverted, by which change the growth was certainly felt more distinctly, and it had caused increasing pain and difficulty in defæcation, so much so that she was unable to work. She had been so relieved by its removal that she was now working hard as a charwoman and did not suffer at all. The second specimen was a uterus with a large subperitoneal fibroid growing from the fundus and with three smaller nodules in the uterine wall. The patient had suffered very little from pain and hæmorrhage, but for some weeks she had had the most obstinate vomiting. *The vomiting came on soon after food* was taken and did not yield to any form of treatment. She was losing flesh rapidly. The uterus was removed by that form of hysterectomy known as the combined method, in which the vaginal portion of the separation was done from below and the separation from the broad ligaments done from the abdomen. The operation was performed in October last and the patient made a good recovery.

Mr. LEONARD GAMGEE read a paper on the Treatment of Mastoid Abscess and the Radical Cure of Suppurative Otitis Media in Children.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—The general meeting of this society was held on Jan. 12th, Dr. Barclay Baron, the President, being in the chair.—The President showed an obscure Naso-pharyngeal Case. A middle-aged man after having a discharge of pus and blood from the naso-pharynx and deafness for several months, began to suffer from severe paroxysmal pain in the right side of the head, becoming gradually worse and more extensive. Later there was numbness of the skin of the same side of the face. Examination revealed a small hard circumscribed swelling with a smooth surface in the upper part of the naso-pharynx.—After a few remarks by Mr. Mayo Collier, Mr. Wyatt Wingrave said that he could detect a hard swelling, apparently on the internal pterygoid plate, which was suggestive of a new growth.—Mr. J. Bark (Liverpool) related a case of Painful Spasm of the Muscles on one Side of the Face cured by removal of a naso-pharyngeal polypus.—Mr. Wyatt Wingrave showed a case of Lupus of the Fauces with extensive ulceration extending down to the larynx, causing much destruction of tissue.—Dr. R Woods (Dublin) expressed a doubt as to the case being lupus and advised specific treatment.—Mr. Mayo Collier gave reasons for similar views and Mr. Wyatt Wingrave replied.—Dr. Dundas Grant showed (1) a case of Emphysema of the Orbit in a labouring man due to blowing the nose; (2) a case of Laryngitis secondary to Rhinitis; (3) a case of Bridge-like Synechiæ between the Septum and the Inferior Turbinal Body without ascertainable cause; and (4) a case of Lupus of the Inferior Turbinal.—Dr Furniss Potter showed: 1. A woman, aged 47 years, with Post-nasal Growths which he considered to be persistent adenoids After giving *his reasons for* this view he mentioned other cases of post-nasal growth in adults which had proved to be *malignant*. 2. A case of a Growth on each Ventricular Band in a man aged 39 years 3. A case of Extensive Papillomatous Growth of the vocal cords.—Mr. Atwood Thorne showed (for Dr. William Hill) a case of Stammering in a youth.—Dr. Dennis Vinrace thought that, the cause being neurotic, the treatment indicated was careful tuition with avoidance of attempts at conversation when excited and attention to the general health.—Mr. Mayo Collier advised the removal of the adenoids present and exercise for the thickened palate.—Mr. St. George Reid observed that in some cases where the velum was sluggish and pendulous and articulation was indistinct it was advantageous to remove a small piece of its posterior edge.—Dr. Brown Kelly (Glasgow) read a paper upon Epistaxis from the Ethmoidal veins. He reported several cases of severe epistaxis in which the stream of blood had been traced to the septum above the anterior end of the middle turbinal. He showed that the vessels ruptured were probably the anterior ethmoidal veins and that these were closely connected with the intracranial circulation. The absence of valves in the veins and the pressure in the longitudinal sinus would allow of a profuse flow in a backward direction. Hæmorrhages from this source were easily checked by packing gauze between the middle turbinal and the septum anteriorly.—Mr. J. Bark observed that recurrent epistaxis in adults usually occurred in the position indicated by Dr. Kelly and that a small plug inserted between the middle turbinal and the septum was effectual and caused little discomfort.—Dr. R. Woods (Dublin) alluded to the constitutional treatment of such cases.—Mr. Mayo Collier and the President also joined in the discussion.—Dr. R. Woods showed a skiagram of a Foreign Body in the Œsophagus of a Child which was successfully removed.

Glasgow Pathological and Clinical Society.—A meeting of this society was held on Jan. 15th, the Vice-President, Mr. Henry E. Clark, being in the chair.—Dr. T. K. Monro and Dr. Charles Workman showed a Heart with Stenosis of Mitral, Aortic, and Tricuspid Valves, with an old Abscess in the Wall of the Right Ventricle. The patient was a female, aged 27 years, who eight years before had suffered from "cold in the chest" followed by rheumatic pains in the legs. From that time she had continued liable to winter cough, while breathlessness on exertion and later palpitation of the heart had supervened. She was admitted to the Royal Infirmary on account of breathlessness and swelling of the abdomen and legs. She died three weeks after admission apparently through weakness brought on by vomiting. In addition to the widespread lesion of the endocardium a small abscess cavity was found on the posterior wall of the right ventricle. This contained greenish caseous pus and some calcareous material. The contents of the abscess presented on cultivation Fraenkel's diplococcus. The lungs showed some passive congestion and the liver, spleen, and kidneys were similarly affected. The case seemed to Dr. Munro to be one of recovery from ulcerative endocarditis, death being due to the effects of the cicatricial valvular lesion.—Dr R. Barclay Ness and Dr. A. R. Ferguson showed a Heart in which mitral and tricuspid stenosis existed; also the brain from the same case, in which the right internal carotid artery was occluded by embolism. There was a history of the patient having suffered from breathlessness and palpitation on exertion since the age of nine years. She was aged 28 years when she died. Ten days before death she had a splenic infarction and death was due to cerebral implication. The embolus was found near the termination of the internal carotid artery at the base of the brain.—Dr. Beatson showed: 1. Multilocular Cystoma of the Left Ovary from a patient aged 67 years. The tumour on section appeared to have the characters of a carcinoma. 2 A similar tumour from the right ovary of a patient aged 35 years. This growth consisted of smooth-walled cysts with cylindrical epithelial lining

Windsor and District Medical Society.—A meeting of this society was held in the Guildhall, Windsor, on Jan. 24th, Mr. W. B. Holderness, the President, occupying the chair.—A collection of Microscopical Sections, chiefly Embryological, of the Chick was shown by Dr. Elgood, Dr. R S. Miller, and an anonymous exhibitor.—Dr. G. E. Hale showed (1) a case of Spontaneous Cure of Popliteal Aneurysm in a man who had had syphilis; and (2) a case of Chronic Disease (? Atrophic Scirrhus) of the Left Breast in an elderly woman who had an abscess 40 years ago, which was lanced in the site of the present disease, and a tumour had been present there ever since.—Dr. A. J. Anderson (Ashford) read a paper on the Use of Anti streptococcic Serum. The first case was that of a primipara who came under his care a fortnight after her confinement with all the signs of puerperal septicæmia. Despite tonic, stimulant, and antiseptic treatment of a vigorous kind her condition became desperate, and three weeks after the birth of the child the serum was brought into use Five injections of 10 cubic centimetres each were made on successive days and the woman made a good recovery. A bacteriological examination showed the presence in the lochia of the streptococcus brevis, staphylococcus, and a "large bacillus." The serum was supplied by Messrs Burroughs, Wellcome, and Co. The second and third cases were those of erysipelas in a severe degree. In the former, treated unsuccessfully by the usual remedies for nearly three weeks, three successive daily injections of 10 cubic centimetres each brought about a great change for the better and the man made a complete, though tardy, recovery. In the latter, which was treated from the outset by the serum, four successive injections of the same strength resulted in a rapid convalescence. Dr. Anderson thought very highly of the treatment, but considered that it should be used with caution because of its depressing effects on the circulation.—A prolonged discussion followed in which the President, Dr. R. S. Miller, Mr. J. Brickwell, Mr. J. H. Tomlinson, and others took part.

North of England Obstetrical and Gynæcological Society.—The annual meeting of this society was held on Jan. 19th at the Owens College, Manchester.—Dr. J. B. Hellier (Leeds) succeeded Dr. A. Donald (Manchester) as President.—Dr. Lloyd Roberts described a case of Suppurating Intra-ligamentous Cyst successfully removed by Abdominal Section. He discussed the technical difficulties of enucleating such tumours and the manner in which they might become septic.—Remarks were made by Dr. A. Donald, Dr. W. Walter, Dr. J. W. Martin, Dr. H. Briggs, Dr. E T. Davies, and the President.—Dr. W. E Fothergill showed specimens of (1) Exomphalos; (2) Pseudo-anencephalus; and (3) Ovarian Cyst with an Unusual History; and a drawing of Hæmatoma Vulvæ.—Remarks were made by Dr. Lloyd Roberts.—The President showed a Microscopic Section of Epithelioma Vulvæ.—Dr Walls related a case of Expulsion of a Dermoid Cyst per rectum during Labour. The specimen he showed, with microscopic section, as an ovarian dermoid. The tumour had apparently been forced downwards by the advancing head till the rectal wall gave way before it and thence it was delivered through the anus. When Dr. Walls saw the case a few days after labour the longitudinal slit made by the tumour in its passage into the rectum was distinctly apparent to the finger. The patient made an excellent recovery.—Remarks were made by Dr. S. Buckley, Dr. H Briggs, Dr. A Donald, Dr. Lloyd Roberts, and Dr. W. Walter.—Dr. S. Rumboll read a paper entitled One Hundred cases of Opening the Abdominal Cavity. He specially described several of gynæcological interest and concluded by discussing the questions of (1) the removal of "cystic ovaries"; (2) abdominal drainage; (3) closure of the abdominal wound; and (4) the after-treatment.—Remarks were made on these points by Dr. Lloyd Roberts, Dr. W E. Fothergill, Dr. A. Donald, Dr. E. T. Davies, Dr. H. Briggs, Dr. W. Walter, and the President.

Dermatological Society of Great Britain and Ireland.—An ordinary meeting of this society was held at Hanover square, W., on Jan. 24th, Dr. H. Radcliffe Crocker being in the chair.—The following cases were shown by Dr. Radcliffe Crocker: (1) A boy, aged eight years, with Prurigo, the disease being limited to the face and hands; and (2) a case of Alopecia in a girl aged seven years. The disease followed an attack of microsporon ringworm.—Dr. J. H. Stowers showed a woman with a Dermato-syphilide of the Nose and adjoining Parts of the Face. He brought the case forward to exhibit the difference between lupus vulgaris of the nose and a dermato-syphilide affecting the same organ.—Dr. D. Walsh sent a case of Nail Disease in a woman. The symmetry of the condition was remarkable.—Dr. F. Rufenacht Walters sent a case of Psoriasis in a child.—Dr. Arthur Shillitoe brought a man with a Widespread Symmetrical Eruption which was diagnosed as a Discoid Form of Eczema Seborrhoicum.—Dr. P. S. Abraham sent (1) a young woman suffering from Leuconychia (together with the condition of the nails she exhibited a band of alopecia running along the margin of the forehead); and (2) a case of Lichen Planus in a girl aged 10 years.—Dr. T. D. Savill brought forward a case of Macular Leprosy in a boy. It had been exhibited at a previous meeting. The pigmentation had increased.—In connexion with the Chaulmoogra oil treatment of leprosy Dr. Crocker remarked that the drug should be given in large doses before it could benefit the patient—up to 100 minims or even in larger quantity per diem Friction with the oil seemed to have a good effect in itself.—Dr. Graham Little showed for Dr. G. F. Still a case of Psoriasis in a Girl.—The cases were discussed by the President, Dr. J. H. Stowers, Mr. Campbell Williams, Mr. G Pernet, Dr. T. D. Savill, Dr. Arthur Shillitoe, and Dr. W. B. Warde

BIRKENHEAD MEDICAL SOCIETY.—A meeting of this society was held on Jan. 12th, Mr. H. Nazeby Harrington, the President, being in the chair.—Dr. T. B. Grimsdale (Liverpool) read a paper on Peritonitis in the Female After briefly discussing the symptoms and diagnosis cases were related in which operation had been performed. The conditions found at the operation were—(1) solid ovarian tumour with twisted pedicle; (2) localised collection of pus containing pure culture of staphylococci; (3) tuberculous pyosalpinx with tuberculous peritonitis; (4) large localised peritoneal blood cyst; (5) ruptured ovarian cyst with four months pregnancy; (6) ruptured tubal pregnancy at the tenth week; and (7) sub-peritoneal fibroid tumour of the uterus in an old woman aged 67 years. In all but the last case the symptoms led to a clinical diagnosis of acute peritonitis being made; in the last case chronic serous peritonitis was diagnosed. The evidence of peritonitis at the time of operation was either the presence of adhesions or the intense red colour of the peritoneum. If the presence of microbic infection be insisted upon as a *sine quâ non* of peritonitis it is probable that some of these cases should not be considered peritonitis at all from a pathological standpoint. However, the clinical diagnosis was the important point from the side of treatment. In cases of peritonitis the importance of rectal or vaginal examination was insisted upon as a point of great importance in helping to discover the underlying condition which gave rise to the attack of peritonitis.—A vote of thanks to Dr. Grimsdale was proposed and carried and a short discussion ensued in which Dr. W. Floyd, Dr. L. D. Temple, and the President took part and Dr. Grimsdale replied.

Reviews and Notices of Books.

Annual and Analytical Cyclopædia of Practical Medicine. By CHARLES E. DE M. SAJOUS, M.D. Illustrated with Chromo-Lithographs, Engravings, and Maps. Vol. IV. Philadelphia, New York, Chicago: F. A. Davies Company. 1899. Pp. 622.

THE present volume commences with a long article on the Diarrhœal Diseases of Infants by Dr. A. D. Blackader of Montreal, and taking into consideration various subjects commencing with the letters I, J, K, and L, finishes with a contribution on the Salts of Mercury by Dr. Sajous.

The manner in which the book is arranged makes it a most convenient one for reference, and under the different subdivisions of each subject the literature of the three years 1896, 1897, and 1898 is epitomised.

Dr. Blackader's paper already referred to gives a good account of the subject with which it deals, the sections devoted to treatment being exceptionally well done.

Dr. N. S. Davis of Chicago writes on Influenza. The section describing the complications of the primary disease will well repay perusal and special stress is laid on the marked impairment of vitality or vital resistance which frequently ensues and which is shown by continued loss of strength and endurance, mental despondency, and increased attacks of bronchitis, pneumonia, and tuberculosis, not only during its active prevalence, but for many months thereafter. such sequelæ are unfortunately but too well known. A large number of interesting cases are quoted illustrative of the nervous and mental phenomena which may present themselves.

Most complete also is the article on Insanity by Dr. George H. Roke of Baltimore. The first requisite for a logical study of insanity is a rational classification—one based upon the known pathology or pathogeny of the disease. As Dr. Roke remarks, the time for a perfect classification of this sort has not yet arrived, our knowledge being too vague or incomplete, but he has made an attempt to carry out what is required and has certainly produced a scheme which is workable. Seven classes or groups of mental disturbance are described, most of them clearly differentiated clinically, but all based upon pathology or pathogeny. We believe the classification to be a sound one; we have not the space to give the grouping which has been adopted, but would refer those of our readers who are interested in the matter to the original paper. Diseases of the Intestines are carefully considered by Dr. Augustus A. Erhner of Philadelphia; and Intubation of the Larynx is described by Dr. F. E. Waxham of Chicago. This operation has found more favour in America than in this country. Dr. Waxham strongly advocates intubation instead of tracheotomy. His figures are certainly very striking. He has performed intubation in 543 cases of diphtheria, all in private practice, and obtained 215 recoveries. In the last 143 cases there were 76 recoveries. In 40 cases in which antitoxin was employed in conjunction with intubation there were 38 recoveries, or 95 per cent. It is difficult, however, to compare these results with tracheotomy as practised in England, for Dr. Waxham performs the operation of intubation at a much earlier stage than that at which tracheotomy is usually done; but nevertheless his results are very striking and should encourage a more extensive trial of intubation in this country.

Another good paper is that by Mr. G. G. Davis on Surgical Diseases of Joints, and the contribution by Dr. Sajous on Laryngitis and Kindred Disorders also contains much that is interesting. The same writer also discusses Leprosy and we especially draw attention to the section on Anæsthetic Leprosy, a subject which has scarcely received the attention which it deserves.

There are several other articles which are also worthy of notice, but we can only mention them—namely, Diseases of the Liver and Gall-bladder, by Dr. Alexander McPhedran of Toronto; Locomotor Ataxia, by Dr. W. B. Pritchard; Disorders of the Mediastinum, by Dr. J. McFadden Gaston, sen., and Dr. J. McFadden Gaston, jun., of Atlanta; and Meningitis, by Dr. C. M. Kay of Philadelphia.

The very valuable article on Malaria by Dr. James C. Wilson and Dr. Thomas G. Ashton of Philadelphia will doubtless attract much attention. The description of the various forms of parasite is full and lucid, the discussion on Pernicious Malarial Fever is also good, whilst the section on Treatment contains a large number of useful suggestions.

Raynaud's Disease. By THOMAS KIRKPATRICK MONRO, M.A., M.D. Glasg., Physician to the Glasgow Royal Infirmary, Examiner in the University of Glasgow. Glasgow: James Maclehose and Sons. 1899. Pp. 250.

THIS volume is intended to give an account of the history, causes, symptoms, morbid relations, pathology, and treatment of Raynaud's Disease. The writer may be congratulated on the success of his endeavours, for he has given us an excellent *résumé* of what is at present known as regards this condition and, what is still more valuable, has supplemented it with the results of his own investigations based upon a very considerable experience.

After a few preliminary remarks on Anatomical and Physiological Considerations a few statistics are given; taken from the wards of the Glasgow Royal Infirmary, from which it appears that one case in 3000 admissions to the medical wards represents the frequency of Raynaud's disease. We agree with the author, however, that this is probably an under-estimate, since the affection is frequently associated with some other ailment, which may be more important from the point of view of survival, and so is more likely to appear in the returns.

The etiology of the disease is well discussed, special stress being naturally laid on the influence of cold. Two types of lesion dependent upon cold are described, chilblain and Raynaud's disease being taken as characteristic instances, and it is shown that whereas in the former the essential lesion is inflammation, in Raynaud's disease it is vascular spasm that produces the clinical phenomena. Dr. Monro states very decidedly that cold not uncommonly is the immediate cause of the first onset of the disease. It was reported to be the case with 22 patients out of 180, 13 being males and nine females, the preponderance of males being due to the influence in them of exposure from occupation. Other etiological factors are also noticed, such as sex, age, heredity, occupation, malarial fever, and sexual disorders.

The characteristic three clinical groups of cases, local syncope, local asphyxia, and symmetrical-gangrene, are described in separate chapters, so that very full consideration is devoted to each, and a table is given showing the incidence of different phenomena in the two series at different ages.

Very interesting is the chapter headed Relations between Raynaud's Disease and other Morbid Conditions. It is a suggestive fact that some abnormality in connexion with the cardio-vascular system is noted in fully 12 per cent. of cases of Raynaud's disease, as shown by the author's statistics, but Dr. Monro points out that this statement is misleading, for a number of cases ought, strictly speaking, to be detached from this group and placed under the heading of Bright's disease, or exophthalmic goitre, or some allied neurosis. It is probable also that in some of the cases where a valvular murmur exists the association is a mere coincidence and that in others the endocarditis and the vaso-motor phenomena depend for their inauguration on some common cause. The association between Raynaud's disease and hæmoglobinuria is also duly commented on, although, peculiarly enough, the association does not appear to have come within Raynaud's experience.

The chapters on Morbid Anatomy and Pathology are quite up to the general standard of the work. The treatment is divided into "general and local," general hygiene in regard to diet, fresh air, and regulated exercise being especially noted. The effects of the administration of quinine, opium, nitrite of amyl, and ergot are carefully set forth; the application of electricity is favourably considered. The book is terminated by a copious bibliography. To those practitioners who desire to obtain a further knowledge of Raynaud's disease we can cordially recommend this book.

LIBRARY TABLE.

The Roentgen Rays in Medical Work. By DAVID WALSH, M.D. Edin. Second Edition, Revised, Re-written, and Enlarged London: Baillière, Tindall, and Cox. 1899. Pp. 257.—The fact of the issue of a second edition of this valuable little work endorses all that we said in its favour on the occasion of reviewing the first edition. The book provides all the information necessary for the medical man who would apply the "x" rays to diagnosis. This edition deals with the development of the subject up to the present time, including a description of new "make and break," tubes, and localisers. An account of the Wehnelt interrupter is added. Dr. Walsh inclines to the opinion that much future advance will be made in the method of producing Roentgen rays by employing statical machines of the Wimshurst type Such a generator would be more convenient for field service The book is more fully illustrated than before, whilst the illustrations maintain the excellence upon which we commented in our notice of the first edition. We should say that the book is a most suitable one for reference on this subject especially in its application to medical practice We may add that the same publishers have issued "The X Ray Case Book" which is designed for recording results as well as the methods and apparatus used, full diagrams of the human body being added for the purpose. Dr. Walsh is responsible for the plan of the book which is sufficient for 50 cases. This book should considerably facilitate the work of diagnosis by means of the "x" rays, and in affording a more systematic way of noting and entering results will most probably lead to better observations.

L'Électricité en Physiologie. (*Electricity in Physiology*). Par M. LÉON MOROKHOWETZ, Professor de Physiologie, Directeur de l'Institut Physiologique à l'Université de Moscow. Première Livraison. Moscow: Imprimerie de l'Université Impériale. 1899. Pp. 32. Price 1 franc.—This is the first part of a work by a competent Russian writer which promises to fill a gap in physiological literature. There are, indeed, numerous isolated articles to be found in journals like Pflüger's *Archiv*, Dubois Reymond's *Archiv*, and our English periodicals which deal with electricity in its medical aspects, but systematic treatises upon this subject are few and not very accessible to English readers. M. Morokhowetz in taking up electricity in its relations to physiology opens up a wide field of research and his first chapter is devoted to the discussion of Electrostatics and Electroscopy. The various forms of apparatus that have been suggested for the production, demonstration, and application of statistical electricity are passed in review and a short account is given of the principle of their construction It is intended that each chapter shall be complete in itself. The present part contains a good portrait of Galvani.

Organic Chemistry. By W. H. PERKIN, jun., Ph.D., F.R.S., and F. STANLEY KIPPING, Ph.D., D.Sc., F.R.S. London and Edinburgh: W. & R. Chambers, Limited. 1900 Price 1*s*.—In response to the representations of many teachers in medical schools the authors have added this little volume as an appendix to their text-book of Organic Chemistry. It consists of a short and clearly written account of the more important substances obtained directly or indirectly from plants and animals, compounds, in fact, of physiological importance. With this little volume, therefore, a very excellent text-book on organic chemistry is completed which is well adapted to the requirements of the medical student. We note that all three parts may now be had in one volume. We expressed the opinion before that such a plan would be better if it could be adopted, as the student has quite enough books to consult without dividing a book on one specific subject into three volumes.

Elements of Practical Materia Medica and Pharmacy. By WILLIAM WOOD, M.B., C.M. Edin. Edinburgh: James Thin. London: Simpkin, Marshall, and Co. 1899.—This is an excellent little guide for medical students attending their first lectures on materia medica. It is an unpretentious work, but contains just that preliminary knowledge of the subject which it is important that the student should grasp at the outset It will assist him especially in connexion with his practical work. It is quite up to date and based on the Pharmacopœia of 1898

The Newer Remedies. By VIRGIL COBLENTZ, Ph.D., F.C.S. Third edition. Philadelphia: P. Blakiston's Son and Co. 1899. Pp 150. Price $1.—This might well be called a dictionary of the newer remedies, the drugs being arranged in strictly alphabetical order, including the vast number of antipyretics, analgesics, and hypnotics, for the existence of which the discovery of benzine in coal tar has been responsible. The information contained in the book is of distinct value, especially in throwing a light upon the nature of substances possessing proprietary names. It will therefore be a useful manual of reference for physicians, pharmacists, and students. This compilation must have ike other nations. A generation [illegible] more has grown up since the Indian Mutiny, and the lessons learned then and in the Crimean campaign have faded from our minds. We have become rich, conceited, and perhaps a little soft—qualities which do not improve our fitness for arduous and novel work like that to which we have been called by the war in South Africa. There are many speculations abroad as to whether the war could have been prevented. Such speculations are not idle, but their time is surely when the trouble is over and there is leisure for retrospect. Disaster is now upon us and no recriminations should be indulged in save with the legitimate hope of staving off further disaster. Fault-finding for the sake of fault-finding must not be counter- anced. The heroism with which life has been given up by officers and men, "by duke's son and cook's son," has never been exceeded in British history. And the noving tale of sacrifice by men who can have no possible esponsibility for the defects in our preparation for war nas excited an unprecedented sympathy for the wounded and killed and for those who represent them at home. If anything were needed to enhance that sympathy it would be found in the narratives of Sir WILLIAM MAC CORMAC and others on the spot who testify to the sublime unselfishness of the wounded soldiers. Mr. TREVES tells of a soldier mortally shot through the abdomen and scarcely able to speak owing to the dryness of his mouth. On the orderly taking some water to him he said: "Take it to my pal first; he is worse hit than me," and that night he died. Such qualities in our soldiers have produced a determination that they and their dependents shall be the peculiar care of the nation and private charity is bent on supplementing the inadequate provision of the State for all sufferers. Nothing can be more right and proper than such a determination.

Fear is felt in some quarters that the patriotic and charitable claims arising out of the war will seriously interfere with the flow of charity in other directions and for other purposes. The *Times* of Monday last in a very forcible article urges the claims of our fellow subjects in the Central Provinces of India who are suffering severely from famine due to drought. 3,000,000 persons or thereabouts are employed on relief works and it is estimated that 50,000,000 people are included in the area affected by the famine. Our contemporary argues that a generous subscription, initiated by the Lord Mayor of London, for the benefit of these fellow subjects will have the best effect on the many enemies of our country and will be the fittest acknowledgment which we can make to those Indian fellow subjects who have so generously proffered their loyalty and support to Her Majesty the QUEEN at the present crisis. We think so too. In other quarters anxiety is expressed lest there should be, as a consequence of the various war funds, a serious falling off in the public contributions to our hospitals. We shall not yield to such fears. We remember that if the country is passing through a period of exceptional anxiety it is also passing through a period of exceptional prosperity. In every branch of trade there is the same report of full work and high wages. The sick, the lame, the halt, and the blind, many of whom have come to grief in the struggle of life, surely constitute a first claim on the profits of prosperous trade. We are neither so impoverished by the war nor so demoralised by our run of prosperity as to the strength of this claim. If our contention is right that most of our present misfortunes arise from our affluence we shall do well rather to double subscriptions to hospitals than to reduce them.

Our sick are cared for and healed in voluntary hospitals—institutions which express the willingness of those who are well to help those who are ill, of those who have means to help those who are poor. The inevitable alternative to such institutions are State or municipal hospitals, and we have ample proof that these are more costly than voluntary hospitals, lack many of their best qualities, and proffer no commensurate advantages. We refuse to believe that the nation will abate its generosity to its voluntary hospitals or allow its sympathy for those who fall wounded in the struggle of life to wane because it is called on to assist with exceptional generosity its soldiers who are fighting so bravely and unselfishly for their QUEEN and country. Let us remember always that those who are suffering through the war—heavy though the roll of sick and wounded, orphans and widows may be—are a small number compared with those who suffer through sickness and accident at home. There is yet one more consideration which forbids us to think that our hospitals will suffer seriously in the coming year from the competition of the war funds—it is that many of our sick and wounded soldiers and their families will come to our hospitals for help. We cannot believe that the public will deprive the hospitals of their necessary incomes because they are also called upon by sentiment and right to help the soldiers.

ON July 27th, 1899, a committee was appointed by the Royal College of Physicians of London to consider the certification and classification of deaths from diarrhœa. The committee had been appointed in response to a representation made by the Incorporated Society of Medical Officers of Health. The report was presented to the Comitia held on Jan. 25th, 1900. The committee found, mainly from evidence furnished by Dr. J. F. W. TATHAM, of the General Register Office, that many different terms are employed to designate the disease officially known as "epidemic diarrhœa," whereby its specific character is in danger of being ignored and great confusion ensues. The results of this confusion are serious and important, since this form of diarrhœa causes a large portion (about one-fourth) of the deaths attributed to zymotic diseases. The committee gathered, from a statement furnished to them by Dr. TATHAM, that his main difficulty lies in the impracticability of picking out from the long list of fashionable but unauthorised synonyms all the deaths which in their nature are indistinguishable from deaths by diarrhœa, and which ought to be called by the authorised name. At present he classes as diarrhœa (and therefore under zymotic diseases) deaths certified as follows: diarrhœa, epidemic diarrhœa, dysentery and dysenteric diarrhœa, intestinal (or enteric) catarrh, and gastro-intestinal (or gastro-enteric) catarrh. The following he does not class as diarrhœa, but as diseases of the alimentary canal (thus excluding them from the zymotic class): gastro-enteritis, muco-enteritis, and gastric catarrh. This second group of cases ought, Dr. TATHAM points out, for the most part to be regarded as identical with epidemic diarrhœa, inasmuch as their age incidence, fatality causes, and general epidemiological characters correspond closely with those of that disease. The committee came to the conclusion that there "is a widespread objection on the part of medical practitioners to the employment of the term 'diarrhœa' in certifying the cause of death. The term is generally held by the public to imply a mild disease, insufficient by itself to cause death. This fact explains the reluctance of the practitioner to employ it in the death certificate, since it may be conceived to imply a stigma upon his own capacity. It is therefore desirable, if possible, to substitute for it some name equally accurate but conveying to the public the idea of a more serious affection, but we regard it as essential that the idea of specificity intended to be conveyed by the term 'epidemic' should be retained." Finally, the committee recommends the College to authorise the use of the term "epidemic enteritis" (or, if preferred by the practitioner, "zymotic enteritis") as a synonym for epidemic diarrhœa, and further recommends that the College should urge the entire disuse as synonyms of epidemic diarrhœa in medical certificates of death of such terms as "gastro-enteritis," "muco-enteritis," or "gastric catarrh." These conclusions were arrived at after the most careful consideration of the members of the committee. They thus bear the stamp of authority, and it is therefore the duty of all practitioners to take note so that accurate statistics may be obtained of the prevalence of the disease in special places or at special times so that due sanitary precautions may be taken to stay the spread of an epidemic.

Annotations.

"Ne quid nimis."

THE ORIGIN OF SEX.

IN a paper read at the Intercolonial Medical Congress at Brisbane in September, 1899, Dr. A. F. Davenport brought forward a number of observations in support of the theory that the sex of the child is determined at the moment of conception and is the opposite to that of whichever parent is at that time in relatively the most vigorous health. He has carried out experiments upon dogs in which by depressing the health of one parent and elevating that of the other he has succeeded in obtaining results which he regards as evidence in favour of his view as to the origin of sex and the power we possess of controlling it. He has also carried out his mode of treatment in the case of 39 families and states that he has succeeded in obtaining children of the sex desired in no less than 32 cases, while in four of the unsuccessful cases no pregnancy followed, leaving only three cases to be reckoned as complete failures. Dr. Davenport considers that Schenck's theory may be taken as directly substantiating his own He would regard the mother affected with glycosuria as the less healthy parent and therefore only capable of giving birth to female children, since, as he contends, the sex of the child is the opposite to that of whichever parent is in relatively the most vigorous health. The number of theories as to the origin of sex is legion and the one under consideration is but a modification of Stackweather's, "that the sex is determined by the superior parent." As has been pointed out by many writers, if we are to accept any theory of the origin of sex it must be one capable of explaining such well-established facts as the preponderance of male births in Europe, of females amongst mulattoes and other hybrid races, of females amongst polygamous animals, and of the equality of the sexes amongst other animals. If we attempt an explanation of even the first of these facts by Dr. Davenport's hypothesis we must at once acknowledge the superiority of the female parent. Stackweather points out the difficulty of proving female inferiority, but at the same time there are few if any writers who attempt to prove female superiority, and Darwin's theory of sexual selection involves superiority in the male sex and entailed upon that sex Dr. Davenport brings forward the fact of the excess of male births after a war as being due to the more enfeebling effect of war upon men than upon women; but it has been conclusively shown, and, indeed, this is the only result that can be regarded as proven, that good nutrition produces a preponderance of females, and it is much more likely that the excess of male births after a war, or an epidemic such as cholera, is due to the want of food and general malnutrition than to physical inferiority upon the part of the fathers. Similar facts have been shown by Düsing to hold good in the case of animals. Thus if food be abundant there is an increase in the number of females, and therefore a further increase in the number of individuals of the species, while if food be scarce a larger number of males are produced and the number of the species tends to diminish. Dr. Davenport also quotes Thury's view that an ovum fertilised soon after its liberation tends to produce a female while if fertilised later produces a male. He concludes without any exact evidence, so far as we can see, that a woman is habitually weakened by menstruation and therefore when impregnated soon afterwards is the inferior parent and likely to bear a female child. In the face of our modern knowledge with regard to the relation of ovulation to menstruation Thury's theory can no longer be sustained as it is quite impossible to tell at what period of time any ovum becomes fertilised. Dr. Davenport's results are certainly striking and it is a pity that he has not increased their value by giving them in greater detail. Similar results have been obtained by the breeders of livestock; thus it is a well-recognised fact that an ill-fed cow is likely to produce a female to a well-fed bull and *vice versâ* We fear, however, that if the method of producing children of any desired sex by influencing the health of the father and of the mother be tried in a large number of cases the numerous exceptions will tend to show that the physical superiority or inferiority of one or other parent is but one of the very many factors that are involved in the complex question of the origin of sex.

MILK, ITS COMPOSITION AND CHARACTERS.

AN *interesting article* with this heading by *Dr. M.* Klimmer of Dresden appears in the January number of the *Archiv fur Wissenschaftliche und Praktische Thierheilkunde.* Dr. Klimmer observes that on hygienic grounds the examination of milk can no longer be relegated entirely *to the hands of the* chemist, but if it is to be distributed to the community in a wholesome condition the supply will have to be placed under the supervision of the veterinary surgeon who must, of course, make himself familiar with the chemical aspects of the question. He then proceeds to describe the characters that healthy milk should possess in terms which we have considerably abbreviated. Pure milk, he says, should be white or after the use of green food yellowish-white in colour, of pleasant sweetish taste, on evaporation having a faint smell suggestive of the animal; placed upon the finger-nail it does not expand, but remains convex, with completely opaque white margin, a test, he remarks, little used but very serviceable. Its viscosity is greater than that of water and diminishes on being warmed more quickly than that of water. Its reaction depends on the test; with phenolphthalein it is always acid; with litmoid or lackmoid it is alkaline; and with litmus paper it is amphoteric, turning blue litmus paper red and red litmus paper blue, which results from its containing two salts of opposite reaction. The acid reaction is due to the primary sodium phosphate, NaH_2PO_4, and the alkaline to the secondary phosphate, Na_2HPO_4, each of which subdues the action of the other on a delicate test. The boiling point of perfectly fresh milk is nearly 1° C. higher, and the freezing-point nearly 1° C. lower, than that of water, a difference which has been used by Raoult as a means of discovering the adulteration of milk with water. When it has become acid this test cannot be relied on. The index of refraction of milk serum varies from 1·347 to 1·3515. The specific gravity at 15° C. varies between 1027 and 1040. It is augmented by removal of the fat globules and diminished by the addition of water. The electrical conductivity is dependent on the fat, sugar, and albumin which it contains and Thörner found that the electric resistance, which is inversely proportional to the conductivity, varies between 180 and 210 ohms, spring water varying from 519 to 1240 ohms. The addition of water consequently augments the resistance of milk and thus furnishes a means of detection. On boiling, good cows' milk does not coagulate, but both colostrum and asses' milk undergo partial coagulation. The reaction on boiling becomes distinctly alkaline. On standing a wrinkled membrane or skin forms, composed of lime salts, albumin, and casein, and a fresh skin appears after its removal. The chief and constant constituents of milk are water, proteids, milk sugar, oil, and salts, but many other substances have been detected in it, though for the most part the quantity is no more than a trace. Amongst these are alcohol, acetic and citric acids, phenol, resorcin, urea, hypoxanthin, leucin, lecithin, cholesterin, sulphocyanide of potassium, amyloid and dextrin-like substances, colouring matters, ethereal oils, carbonic acid gas, nitrogen, and oxygen. The proteids consist of casein, lactalbumin, lacto-globulin, and a nucleo-albumin. The limits of the quantity of the casein are from 2·9 to 5 per cent. *The albumin is only in the* proportion of one-half per cent. The amount of milk sugar varies from 4·5 to 4·93 per cent. The acidification of milk sugar or its conversion into lactic acid is effected by many ferments, but essentially by the bacterium acidi lactici and an unorganised ferment contained in the gastric juice. Further active agents are the bacterium lactis aerogenes, bacterium acidi lactici, bacterium limbatum acidi lactici, sphærococcus acidi lactici, streptococcus acidi lactici, and micrococcus acidi lactici, with others. In regard to the salts, which usually amount to from 0·7 to 0·8 per cent., the following figures, which form a part only of a much fuller table, give the mean proportion of each of the constituents: K_2O, 24; Na_3O, 10; CaO, 22; MgO, 2; Fe_2O_3, 0·3; P_2O_5, 26; Cl, 14; SO_3, 3. It is to be especially noted that milk contains neither nitrates nor nitrites. The percentage quantity of water is given by three good observers as 87·75, 87·5, and 86·23. The quantity of fat in milk varies to an extraordinary extent—viz., from 2·5 to 7 per cent.—*the average being from* 3 to 4 per cent. The oil globules in milk vary in diameter from 0·0001 to 0·006 millimetre. The weight of each particle has been estimated to be about 0·0000004 milligramme. Their number in one litre of milk containing 3·5 per cent. of fat is stated by Masato Toyonaga to be from 691 to 2291 billions with a superficies of from 512 to 719 square metres. The largest oil globules are contained in the milk of Jersey cows, and in morning as compared with evening milk. The fat of milk consists about 92 per cent. of the triglycerides of stearic, and oleic acids, and the remainder of specific butyrin, capronin, caprylin, and caprinin, besides traces of lecithin, cholin, and cholesterin. The circumstances ing the amount of fat in milk are numerous, as idiosyncrasy, breed, age, period of lactation, sexual excitement, mode and time of milking, exercise, and food and hygienic surroundings. Low-country (Holland) cows supply a large quantity of milk, but with less fat in it than those of mountainous regions. Cows begin to yield milk in the course of the third year, which improves in quality to their seventh year, and then gradually deteriorates. In good milch cows the period of lactation lasts about 300 days, and in that time a cow produces from 4·5 to 7·5 its living weight of milk. During the rutting season, according to a widespread belief, the yield of milk is less in quantity but richer in quality. This, however, has been contested. As a general rule it may be said that the briefer the interval between two milkings the greater the percentage of the milk in dry residue and especially in fat, and the smaller the quantity that can be obtained at each time of milking. At each milking it has been shown by numerous observers that the milk gradually becomes more charged with fat, whilst the amount of dry residue remains constant. Thus as a mean of four experiments the quantity of fat contained in the first portion drawn was 0·70 per cent., whilst in the last portion it was as much as 4·73 per cent., the quantity of casein and sugar and salts remaining almost the same in both. *Hence, as Dr. Klimmer remarks, by fractional milking any desired proportion of fat can be obtained.* The influence of food upon the quantity and quality of milk is very great. Increase of proteids in the food increases the quantity of milk, but evidence is conflicting as to whether it increases the fat. Addition of fat to the food increases the quantity of fat. Dr. Klimmer, without expressing a strong opinion one way or the other, seems to doubt the advisability of using distillers' wash for cows intended to supply milk for the nursery. Dr. Klimmer's essay, we may say in conclusion, contains much valuable information and will bear careful perusal by those interested in the supply of wholesome milk.

THREE CHURCH SOCIETIES.

THREE conferences were held recently at the Westminster Palace Hotel under the auspices of the Church Society for the Promotion of Kindness to Animals, the Church Sanitary Association, and the Funeral Reform Association. Mr. J. G. Butcher, M.P., presided at the meeting of the first-named society, and among the speakers were the Hon. Mrs. Henniker and the Hon. FitzRoy Stewart. It was unanimously resolved that a competent man should be sent out to South Africa to examine into the condition of horses on the battle-field and to report thereupon with a view to bring about an international agreement extending to persons relieving the sufferings of wounded animals on the battle-field the same protection as is now afforded to men who succour wounded soldiers. Dr. William Collingridge, medical officer of the Sanitary Authority for the Port of London, in presiding at the meeting of the Church Sanitary Association, said that manifold agencies for the promotion of sanitation had done good work, but their work was of necessity slow; hence it was that some stronger and more direct agency, such as the Church Sanitary Association, was required as a means of reaching the masses through the existing organisation of the Church. Amongst those who supported this view were Dr. Christopher Childs, the Rev. Septimus Buss, Major Poole, and Mr. Hugh Munby. It was unanimously resolved that an incalculable amount of sickness, suffering, misery, and death would be prevented if the clergy realised what invaluable help they could render in promoting the observance of sanitary laws and in counteracting and eradicating insanitary habits and customs. The speakers who supported the Right Hon. James Lowther, M.P., the chairman of the meeting of the Funeral Reform Association, were the Earl of Stamford and the Rev. Canon J. Erskine Clarke. The following motions were duly carried: "That excessive funeral floral decoration is to be greatly deprecated," and "That the burial of the dead should not be unduly delayed and the mode thereof should be inexpensive and innocuous."

TWENTY YEARS OF EPIDEMIC DYSENTERY IN JAPAN.

FOR many years past dysentery, whether epidemic or sporadic, has troubled us but little in Great Britain, but the history of the disease, more especially as to the epidemic of 1762, bears record to the mischief which in times gone by it wrought in these islands. Whether epidemic dysentery has disappeared for ever from our midst, and whether it has done so as the result of sanitary measures are questions which in our present state of knowledge are somewhat difficult to answer. But even if it be gone for all time there is in a sense a satisfaction in reflecting upon what we have lost in order that our gain may appear the more. Dr. Stuart Eldridge of the United States Marine Hospital Service, who is stationed at Yokohama, has recently presented to the United States Government an interesting account of the behaviour of epidemic dysentery in Japan. Dr. Eldridge tells us that the statistical records of the disease in Japan date back to 1878, and that up to 1880 it manifested itself almost exclusively in the southernmost of the islands of which Japan consists. Since then, however, the march of the disease has been slowly, but, as events have now proved, surely, towards the north of the group, and a map is furnished with the report before us showing the dates at which the several provinces of Japan became first invaded and the extent to which the several populations have suffered. The progress of the disease northwards has been at times temporarily checked by natural obstacles such as mountain ranges and straits of water, but in the end, following the lines of greatest trade communication, it has vanquished, and last year it obtained a footing in the island of Yezo which, Dr. Eldridge reports, it now threatens to invade entirely. And now as to the sickness and death toll which epidemic dysentery has exacted for the last score of years in Japan. In 1878 the reported cases numbered 1118 and the deaths 206, in 1893 there were 167,305 cases with 41,282 deaths, and last year (1899) 125,939 cases with 26,709 deaths, the average fatality-rate for the whole period under review being nearly 25 per cent. Efforts to control the disease do not seem to have met with much success, but it is hoped that as the people themselves come more clearly to comprehend that the restrictive measures are for the good of the whole community more advance will be made. It is during the summer and autumn that the disease prevails, and it has been noted that low and damp localities come in for a large share of attacks, while the rural districts, having regard to the extent of their populations, suffer more heavily than do the urban. The chief agent in the spread of the disease is, Dr. Eldridge thinks, water, and this fact is, it seems, a possible explanation of its increased incidence on rural as compared with urban districts. Night-soil is used freely to manure the land and this manuring is obviously more common in the rural districts. Hence when the rains come the water supplies of the rural districts are more likely to be polluted than are the urban. But, curiously enough, the distribution of cholera in Japan in the epidemics which have occurred since 1877 has not followed that of dysentery, albeit cholera is undoubtedly a water-borne disease. The Japanese apparently account for this discrepancy by assuming that the acid fermentation to which the night-soil is submitted before being placed upon the fields kills the cholera bacillus, and they assume, moreover, that future bacteriological investigations will show the bacillus of dysentery to be more resistant under these circumstances than is that of cholera. The Japanese people are, in Dr. Eldridge's opinion, far from adaptable to the necessary hygienic measures for preventing the spread of dysentery. They are quite ignorant of the elementary principles of prevention and there is rarely skilled advice available. Furthermore, we are told that in cases of sudden outbreak of disease religious festivals are organised with a view to propitiating the Supreme Power, and that these functions have the effect of gathering together the people from infected as well as healthy localities, there to indulge in practices likely to contribute to the spread of infection and to reduce the powers of resistance of the individual. Dr. Eldridge goes fully into the symptoms and pathology of the disease, but into these we have no space to follow him. He gives, too, a useful summary of the progress as to the bacteriology of dysentery, more especially of Dr. Kiyoshi Shiga's recent work in this direction. Dr. Shiga claims to have found the specific bacillus of dysentery, or, at any rate, of that variety of the disease now seen in Japan. Morphologically it strongly resembles the enteric fever bacillus and has a tendency to produce involution forms. This, the bacillus dysentericus, is killed by exposure to 68° C. for 20 minutes; it has no active movements and flagella have not as yet been demonstrated. Dr. Shiga also claims to have discovered an artificial serum for the treatment of dysentery and certain figures as to a diminished fatality-rate among patients so treated would appear to be of a hopeful nature.

FIRST MEMOIR OF THE LIVERPOOL SCHOOL OF TROPICAL DISEASES.

THE Liverpool School of Tropical Diseases has issued its first memoir under the title of "Instructions for the Prevention of Malarial Fever: for the use of Residents in Malarious Places." The causes of malarial fever are explained to be due to the presence of certain minute parasites called hæmamœbidæ in the corpuscles of the blood. In order to produce an attack of fever about 250,000,000 parasites must be present in the body, while in severe cases a billion or more may be present. In sufficient numbers they may be easily detected with the aid of a strong microscope in a drop of blood drawn from the patient by pricking with a needle. The sudden rises of temperature which occur in this disease, and which are accompanied by shivering (ague), are due to the parasites scattering their spores in the blood-fluid. The parasites grow up together and scatter their spores simultaneously, causing an immediate rise of temperature and shivering. After a variable number of attacks of fever the parasites may largely decrease in number, leaving the patient free from fever for a time. At any moment, however, the number of parasites may increase again, either spontaneously or through the patient's exposure to the rays of the sun or to chill or fatigue. Between the relapses the parasites continue to live in the patient in comparatively small numbers. After they have become extinct no relapses will occur, unless as the result of a fresh infection. Quinine kills the parasites. All parasites or their eggs pass in some way or other from one host to another—that is, from an infected individual, animal or plant, to a healthy one. Suctorial insects give great facilities to parasites for passing from one host to another. Upon allowing a person infected with malaria parasites to be bitten by mosquitoes of the kind called anopheles dissection of the mosquito will disclose the parasites growing in the mosquito.

If, on the other hand, the mosquito be allowed to bite healthy persons nothing like the parasites will be found in them. Malarial fever has been proved to be communicable from the sick to the healthy by the agency of mosquitoes—the anopheles. The question arises, If malarial fever is only carried from man to man by mosquitoes how comes it that the disease is connected with stagnant water, rainfall, or disturbed soil? *It is* because the anopheles do not breed in vessels of water, tubs, &c., in which the ordinary kinds of mosquitoes breed, but, as a rule, only in stagnant puddles of water on the ground. Such puddles most commonly exist in low-lying flat localities, especially where the ground tends to be marshy and, of course, during continuous rains. They also accumulate in places where the ground has been excavated, embanked, or trenched. Hence it is easy to see how the idea that malaria arises from marshes gained ground, and that it was due to a miasm, or mist, which rises from damp soil. The germs of malaria themselves do not rise from the soil. It is the carriers of the germs, the anopheles, that do so, or rather that rise from the pools of water on the ground. This fact also explains why draining the soil so often removes malaria because it drains away the breeding pools of the anopheles. It is only the female anopheles which sucks blood, the males living on fruit and leaves. After feeding on a man or an animal the female generally sleeps gorged all day on the wall of a room or other place. Every few days she has to fly back to the water where she lived as a larva to lay her eggs, and returns afterwards, probably to the place where she first obtained food. Hence mosquitoes which feed on human beings generally breed in water close to houses. Males can be distinguished from females by their possession of feathery antennæ on their heads. Directions in the modes of prevention of malaria include the avoidance of being bitten by mosquitoes as much as possible. Mosquitoes or their larvæ, especially anopheles, should be killed. They should be prevented from breeding around houses. The use of mosquito nets is essential above all things. Patients suffering from fever or who have lately suffered from fever should always remember that they are capable of spreading the disease to others through the agency of mosquitoes and are even capable of re-infecting themselves through the same agency. They cannot be too careful to avoid being bitten. For the destruction of mosquitoes a search is to be carefully made in and around the house for vessels and pools of water; and if there are many mosquitoes in the house it is highly probable that their larvæ will be found close by. Small pools on the ground containing green water-weed, especially rain-water puddles, are their favourite haunts. All useless collections of water in which mosquitoes breed should be drained away if possible. If this cannot be done recourse must be had to the habitual use of substances, such as kerosene oil, which destroy the larvæ by choking their air-tubes. Cisterns and wells of drinking water should be kept covered in as much as possible. Much useful information is condensed in a very limited space in this welcome booklet, which is issued from the University Press of Liverpool.

VALVULAR DISEASE IN OLD AGE.

IN the *American Journal of the Medical Sciences* for December, 1899, Dr. Robinson insists on the great importance of watching carefully for the first expressions of cardiac insufficiency in old age. When dropsy begins to appear about the ankles or when the serous cavities contain fluid in notable proportion the prognosis is grave and the warding off of progressive œdema and accumulation of fluid is very difficult. The best results which he has seen in such cases have been obtained by the use of Trousseau's wine or the diuretic wine used at the *Hotel Dieu, whose good results (even if temporary)* are noteworthy. The diuretic wine is composed of digitalis, squill, juniper berries, potassium acetate, and white wine, and is prescribed in dessert- or table-spoonful repeated every three to eight hours. Dr. Robinson points that it is an error to give cardiac tonics in large doses. Small doses frequently repeated are more effective. He also deprecates the indiscriminate combining of a large number of drugs on the "shot-gun" principle. Whenever an attempt is made to give power too suddenly to an already overtaxed or enfeebled heart the danger is that of overstepping the mark, of bringing about cardiac over-stimulation, followed by failure and the liability therewith of a fatal termination. Cardiac slowness (bradycardia) is often an indication of intra-cardiac changes or may be the consequence of a gouty diathesis or toxæmia, and in the latter case the use of suitable eliminative remedies (lithia, piperazine, and restriction of diet containing urates) is attended with excellent results. He also contends that torpidity of the liver is often a primary factor in this undue slowness of cardiac action, and when other indications exist pointing in this direction, small doses of calomel and soda, or grey powder, repeated a few times during the course of a week or fortnight will often bring about great improvement. Where a long-continued course of treatment is indicated it is well to abandon the use of mercurial preparations and to use instead small and frequent doses of podophyllin, ipecacuanha, rhubarb, and soda. After such a course senile hearts are often practically rejuvenated, for a time at least, and enter upon a new lease of life. In gouty cases and in those where symptoms of angina may be present he advises also the use of Contrexéville water. He mentions several cases in which the gouty condition of the blood has been favourably modified in a striking manner by the use of Contrexéville water for some weeks, and states that the elimination of uric acid from the economy by its action seems at times exceptionally great.

VACCINATION LEGISLATION: A BAD POINT.

HOW many points of law have been raised and argued by the opponents of vaccination since the Act of 1867 was passed it would be impossible to reckon or even to estimate. Considerable ingenuity has been expended on them; some have been good, some indifferent, and some bad, while to the last group, the one upon which the Divisional Court was asked to rule in "Over *v.* Harwood" on the 26th ult., must beyond doubt be assigned. An order had been made under the thirty-first section of the Act, requiring the defendant to have his child vaccinated. In order to prove that the order had not been complied with the vaccination officer deposed that he had not received any certificate of successful vaccination. Six Surrey justices had been satisfied on this evidence that their order had not been obeyed, but had been induced to state a case in order that a learned counsel might argue in the High Court of Justice that evidence of no notification was not evidence of no vaccination. Mr. Justice Channell pointed out that the absolute proof of a negative by direct evidence is not always possible, and that recourse must sometimes be had to *presumption*, some evidence being given upon which that presumption may be based. He added that the law provides that vaccination shall not only be performed but notified and that if there had been no notification in the case before the court someone had neglected a duty. He therefore was of opinion that the absence of notification was *primâ facie* evidence that the child had not been vaccinated, and that if the magistrates were satisfied and required no further proof the court would not interfere with their discretion. It is not easy to see what the anti-vaccinationists responsible for such an appeal expected to gain by it. *They could hardly have* expected that vaccination officers would in future be compelled to produce the child or some one who had examined the child, which would be the best way of proving the case if it were possible to do it, and they must have known that it would be clear to everyone that no injustice could possibly arise from the evidence of non-notification being accepted, because if the natural inference were incorrect it could, and of course would, at once be rebutted by direct evidence that the child had in fact been vaccinated, in which case the omission to notify according to law would still remain. The appeal, therefore, was one in which there was no prospect of success, while no grievance could arise as a consequence of its failure.

THE INFLUENCE OF VARIOUS STIMULI ON CILIARY MOTION.

NUMEROUS essays on cilia, their structure and motion, have appeared since the researches of Professor Sharpey were first published in the "Cyclopædia of Anatomy and Physiology" about the year 1836 and the latest one is written by Dr. Bergel and published in the January number of Pflüger's *Archiv*. For his material, instead of scraping off as usual the epithelial cells of the pharynx of the frog, he injects subcutaneously into that animal a centimetre of a 1 per cent. solution of hydrochlorate of pilocarpine, or the same quantity of a ¼ per cent. solution of curara, and finds in the course of a few hours that a considerable number of ciliated corpuscles float in the secretion that accumulates in the throat. He proceeds to point out that as ciliary movements can be seen in these corpuscles after the lapse of two days from the death of the animal there can be no question of their entire independence of the nervous system. The motor centre, if the expression may be allowed, must be in the cell itself. On examination of the secretion not only groups of cells may be seen with the cilia in action, but also rounded bodies that appear to be the outer portion of the protoplasm of the cells crowned with cilia particles which have thrown off the cell-wall and are therefore destitute of an investing membrane. As a rule the larger the fragment of the protoplasm the shorter are the cilia, and *vice versâ*. Those fragments which possess the longest cilia are best adapted for observation and the activity of the movement of their cilia may be followed as it gradually dies out until there are only two or three complete vibrations in the second; even then it may be seen that the cilia on each fragment of protoplasm do not vibrate simultaneously but succeed each other in an orderly and successive manner. The forward stroke of each cilium is more sudden and vigorous than the return stroke, and in both movements the cilium is S shaped or undulatory in form. As the protoplasmic store of reserve force fails the cilia one after another cease to move till one alone remains in action; and so again if a cell with resting cilia be stimulated first one and then others begin to vibrate till all, it may be, are brought into action. In regard to the effects of stimuli of various kinds on the detached masses of protoplasm with cilia it was observed that when the movements of the latter had become slow the contact of a blood corpuscle or the cilium of another cell immediately caused them to become more frequent, a response to mechanical stimulation that is clearly of importance under normal conditions in promoting the movement of particles of dust in the respiratory passages outwards and in hastening the onward movement of the egg in the oviduct. In regard to the effects of heat it appeared that no recovery of motion took place if the cilia were perfectly quiescent, but if they were still vibrating the movements became more and more vigorous till a temperature of 95° F. was reached, after which they gradually diminished till at a temperature of 108° F. they entirely ceased Dr Bergel next proceeded to experiment on the influence of the access and withdrawal of light on ciliary motion, and found that as the light was reduced the movements of the cilia became slower and feebler and were ultimately arrested. If they were previously moving energetically the time elapsing before arrest occurred might be as much as three-quarters of an hour, but if feebly then in a much shorter time, perhaps not exceeding from four to eight minutes. If after complete arrest a bright light were thrown on the stage of the microscope a latent period elapsed (sometimes lasting as long as two minutes) and the movements of the cilia recommenced, some beginning to move earlier than others and sometimes resting for a moment or two as if a gathering up of force were required for their full play. When the alternation of light and darkness was frequently repeated the corpuscles with their cilia appeared to become exhausted and failed to recover themselves completely. An explanation of the stimulating influence of light is offered by Dr. Bergel who suggests that light promotes oxidation which again increases the production of heat which undergoes conversion into work. In this respect these rudimentary organisms agree with what has been observed in frogs by Moleschott and in rabbits by Pflüger and von Platin. When the nerve stores of the protoplasmic masses are used up no more oxygen can be absorbed and the cilia cease to respond to the influence of light. Lastly, in regard to the stimulus of electricity it appeared that in particles with completely motionless cilia feeble currents failed to excite any movement, but stronger ones caused after a latent period of some duration a few cilia to move, then more until all were in action; on breaking the current the motion continued for some time and then gradually ceased. Excitation by means of electricity of active moving cilia gave no results from which any positive conclusions could be drawn.

PARIS CONGRESSES AND PARIS HOTELS.

THE Committee of Organisation for the International Congress of Medical Deontology or Medical Ethics have just issued a circular concerning the question of hotel accommodation for the intending members of the Congress. They urge that no time should be lost in securing rooms, and enclose the circulars of four French agencies which on former similar occasions have given satisfaction to members of scientific congresses. The question, however, for us to decide is whether as members of the British public we do not exercise a better control over English agencies. In any case, ephemeral agencies started merely in view of the Exhibition should be approached with some caution. The safest rule to observe is to resort to those firms which have a reputation to maintain, and that, too, among the British public. This observation does not imply a condemnation of French agencies because in some cases, and perhaps unfairly, French firms give themselves more trouble to please English patrons than their own countrymen. This is notably the case with regard to the *Messageries Maritimes*. The English passengers who travel in these French steamers to India, the Far East, and Australia are, we have been assured by experienced travellers, treated with more deference and consideration than are the French passengers. We do not, of course, flatter ourselves that this is done from any other motive than that of competition against the English lines, but, still, the fact remains Whether the same partiality will be shown by French travelling or tourist agencies we are not able to say, but of one thing we are quite certain. The hotels mainly frequented by the English and the Americans are the dearest, the cleanest, but the most unpleasant on the continent. The waiters, while expecting much larger gratuities, are not always attentive or civil, and the cooking is entirely ruined by the unappreciativeness of the British and the Americans The experienced continental traveller of whatever nationality will always give such hotels a wide berth. As the French agencies are patronised mainly by French people, their hotels are likely to be inferior from the sanitary point of view and superior from every other point of view; more especially are they likely to be cheaper. For instance, one agency undertakes to provide lunch, dinner, and room for 10*s.* a day. Another agency charges 12*s.* a day, but this includes coffee and rolls in the early morning and wine at meals. Before, however, venturing to say more on this question and assuming the responsibility of making any definite recommendation, our Special Correspondent, who will deal with the Paris Exhibition and the scientific congresses connected therewith, will make inquiries on the spot, visit some of the hotels, and report.

DIPHTHERIA STATISTICS IN NEW YORK.

WE are indebted to a correspondent for the following statistics of diphtheria in New York City during the semester January–June inclusive, 1899. The information will be read with interest in connexion with a paragraph in our New York correspondent's letter in THE LANCET of Jan. 13th (p. 138). The figures denote total cases under all treatments (serum of all makes and no serum).

TABLE I.

Disease.	Cases reported.	Deaths.	Percentage of mortality.
Diphtheria	4789	780	16·3
Croup	315	154	48·8
Total	5104	934	18·3

TABLE II.—*Totals under Purview of the Department of Health and Treated with the Serum of its own Manufacture after Bacteriological Diagnosis.*

Cases determined true diphtheria (Klebs-Löffler bacillus)	2468
Deaths	780
Percentage mortality	31·2

Note.—These sums are too small by the figures for the week ending Feb. 19th, wanting in the official city record.

With respect to the difference in diphtheria mortality as between the pre-antitoxin and the post-antitoxin periods the letter before us states that the line of division is almost exactly Jan. 1st, 1895, and the writer continues as follows:—"I have recognised the importance of this point, but I have omitted the figures for the following reasons. Diphtheria statistics of the old New York City and up to Jan. 1st, 1898, cover only Manhattan Island and the annexed northern (Westchester) territory in the present city limits, or bills of mortality, the boroughs of Manhattan and the Bronx. And the figures before about 1880 refer only to the present borough of Manhattan. Since that division period the bills of mortality of that which is known as New York add to the present boroughs of Manhattan and the Bronx the old city of Brooklyn (for six preceding years coterminous with the county of Kings and before Jan. 1st, 1882, distinct entities), the county of Richmond, the present borough of Queens, which comprises the former municipality of Long Island City and a major fraction of the old county of Queens. I am convinced that it is absolutely impossible to establish figures for the comparison of the present area of New York City with the same territory before the consolidation which went into effect on Jan. 1st, 1898. This would involve the study of the following municipalities, Manhattan and the Bronx, Brooklyn (which for six years includes the outlying county of Kings and before that time excludes the county), the rural county of Richmond (Staten Island is geographically coterminous), Long Island City, and a portion of the county of Queens. Out of these elements it might be possible to secure somewhat accurate figures of Manhattan Island for many years, of Manhattan and the Bronx for 16 years, of Brooklyn for many years, of the county of Kings for a few years, of the county of Richmond poor accounts for a few years, while, lumping Long Island City and a portion of Queens county, it would be impossible to establish any figures for these at all. Since Jan. 1st, the city of New York represents four times the area and double the population of what it meant before that date, and because of the many complications it is impossible to establish comparable figures. As you glance over these lines you may arrive at a conclusion, though I do not deny that my explanation is involved and complicated. Yet it is as clear as crystal in comparison with the tangled data into which it would be necessary to plunge to establish comparative figures before and after Jan. 1st, 1898."

ANTONIO MACEO'S SKULL.

THE *Revista de Medicina y Cirugia* of Havana publishes an "anthropological study," by Dr. Montalvo, Dr. de la Torre, and Dr. Montane, of the skull of the Cuban patriot, Antonio Maceo. The most noteworthy point is the existence of an interparietal, or, as it is sometimes termed, an "inca" bone, from the theory that it was universal amongst, and distinctive of, the old Peruvian race. This, however, was shown by Anoutchine[1] to be erroneous, for after examining many thousands of skulls in various museums he found the bone in only 6·8 per cent. in Peruvians, in 1·5 per cent. in negroes, and in 1·3 per cent. in Americans. Maceo was, of course, of mixed race. The general character of the cranium approximates to that of the white race and indicates a man of remarkable capacity. The rest of the skeleton inclines more to the negro type and shows that he must have been a man of Herculean strength.

URIC ACID AND LEUCOCYTOSIS.

IN an article on the excretion of uric acid with special reference to its connexion with leucocytosis, Dr. Carstairs C. Douglas of Glasgow published in the January number of the *Edinburgh Medical Journal* the results of 97 simultaneous quantitative determinations of uric acid and leucocytes made on seven persons in good general health (one of them pregnant) and 35 patients suffering from various diseases. In the course of a short summary of recent views regarding the origin of uric acid within the body he says that the theory of uric acid formation which has awakened the greatest amount of interest of late years, and which is apparently supported by many clinical and experimental facts, is that associated with the name of Horbaczewski, who holds that uric acid is derived in the body from the disintegration of proteids containing nuclein, notably from the leucocytes. Objections to this theory have, however, not been wanting. Richter, for instance, argues that, according to Horbaczewski, the maximum excretion of uric acid after food corresponds with the maximum number of leucocytes, whereas it should really follow the latter if due to a breaking down. Again, it has been pointed out that, if the uric acid be due to disintegration of leucocytes, in cases where the former is increased the phosphoric acid excretion ought also to be augmented, but it has in reality been found that exactly the converse may take place. From his determinations of uric acid and leucocytes Dr. Douglas concludes that on the whole there is a discrepancy between the amount of uric acid thrown off from the body and the number of leucocytes. No doubt there are striking instances in which there appears to be a marked parallelism between the two; but on an equal number of occasions the converse can be shown to hold true. That nuclein containing tissues on ingestion may increase the amount of uric acid excreted is proved by the effect of the administration of nuclein and of thymus, but the observations which he has made do not support the view that normally the source of uric acid is to be found in the nuclein of the leucocytes. His analyses showed among other things (1) that uric acid varies much less with diet than urea does, and (2) that in prescribing a diet for the gouty it is inadvisable to order vegetables promiscuously, as is too often done, but those which are poor in proteid ought to be selected, and sweetbread and similar tissues rich in nuclein ought to be rigorously excluded.

MEDICAL MATTERS IN RANGOON.

THINGS do not seem to have been working well of late in the small medical world of Rangoon, according to the *Rangoon Gazette*, in its recent reports of proceedings connected with the Dufferin Hospital and the General Hospital of that place. We find it difficult to give a *précis* of the facts within a reasonably short compass. As regards the Dufferin Hospital, it appears that in 1885 it was determined that the best method, as far as Burma was concerned, of assisting the Countess of Dufferin in attaining her object by the establishment of a national association for providing female medical aid to the women of India was to teach some Burmese women something of scientific midwifery, that having been found to be one of the most pressing practical requirements of the native population. The Rangoon Dufferin Maternity Hospital is the only hospital in Burma largely supported by voluntary contributions and it was established for the purpose of affording opportunities for the practical instruction of Burmese women in midwifery. Sufficient funds have been collected to build a larger and better hospital than that which formerly existed. On the opening of this new institution the central committee in India demanded that a lady doctor with an English qualification should be placed in charge with leave to pursue private practice. This has been done, but contrary, it is alleged, to the advice of the provincial medical authorities The consequence has been that the former lady medical officer, who had considerable experience and was a fluent teacher in the Burmese language, has been replaced by a lady with diplomas of a higher grade, but who is said to be unacquainted with Burmese. Finally, proposals from the central committee in India have been adopted by which the services of the honorary medical officers of the hospital have been dispensed with and the institution has been, or is to be, placed under the civil surgeon of the station. It is alleged that the proposals of the central committee in India have arisen from an entire misapprehension and ignorance of the peculiar local conditions which the institution as hitherto conducted has very satisfactorily met, and a public memorial is about to be presented to the Viceroy of India asking for an inquiry and protesting against the action taken by the Lieutenant-Governor in the matter. The small hospital which originally existed at Rangoon, it may be remarked, is alleged to have been successfully carried on and was largely wanted by the Burmese women. A Dufferin Hospital in India is understood to be for all diseases which are, for religious and caste reasons, to be treated exclusively by lady doctors, but the hospital at Rangoon is a maternity and gynæcological hospital only and the Burmese women are notoriously not affected by any caste or social restrictions which affect Indian races and it is quite customary for them to consult and receive treatment at the hands of the male sex. As the matter stands it seems to us to turn upon a question of what is best and most advantageous for the native community, for the benefit of whom the institution exists, and we should regret to learn that the rules of the Dufferin Association were prohibitory of what has been hitherto pursued with presumably manifest advantage to those mainly concerned. The matter seems to require further attention on the part of those who have the requisite authority to give it fair and impartial consideration so as to arrive at that conclusion which is best for the interests of the native population. As regards the General Hospital at Rangoon it appears, according to an article in the *Rangoon Gazette* of Dec. 29th, 1899, that among other matters considered at a meeting of the hospital sub-committee, a report by Colonel Little, I.M.S., Inspector-General, who had inspected the hospital on Nov. 20th, 1899, came under notice. The Inspector General evidently found a good many points which he regarded as far from satisfactory, as will be seen from the following quotation from our contemporary :—

> "The present quarters for menial servants are too crowded and too close to the main buildings. These, together with the contagious disease ward and the servants' latrine, should be removed to some distance from the hospital well apart from other buildings. ... The hospital affords accommodation for 461 beds. The daily average indoor attendance is 307... The nursing staff appeared to me inadequate for the requirements of this large hospital. ... The superintendent drew attention to the necessity for a hot water service laid on to the hospital, a linen room, a dhobie room, and a disinfecting and sterilising room. The municipality, I believe, are prepared to supply them; they are essential to the proper working of the hospital on modern principles. ... Two medical officers, one resident medical officer, two assistant surgeons, and eight hospital assistants are the staff for this large hospital of 461 beds with a daily average attendance of 307 patients. This is a weak staff. ... The senior surgeon has office duties to perform and other administrative work which should fully occupy his time. The junior civil surgeon is in charge of police cases, including post-mortems, and of the contagious disease hospital, in addition to his share of the ward work and operations. There is a good deal of useful operative surgery, and these cases require careful dressing daily on antiseptic principles, to which the house surgeon can scarcely give his personal attention in all cases, so that the dressing must be largely conducted by the hospital assistants, a class of men whose work is seldom other than unsatisfactory where aseptic surgery is concerned. I do not mean to disparage a very useful and hard-working body of men, but think their education and training is not such as to guarantee efficiency in the matter of aseptic surgery or an intelligent knowledge of the principles on which it is worked."

It is understood that a new hospital is to be constructed as soon as funds can be provided for the purpose.

A CASE OF COMPLETE NECROSIS OF ONE SIDE OF THE MANDIBLE.

AN interesting case of necrosis of the mandible is recorded in the current issue of the *Journal of the British Dental Association* by Mr. W. H. Dolamore. The patient, a boy, aged four years, was taken to the dental department of the London Hospital with a large swelling on the left side of the face. The swelling appeared five weeks previously and a lower deciduous molar was removed. The swelling, however, increased and at the time of being seen by Mr. Dolamore there was a profuse discharge of pus from the gum and the remaining left lower deciduous molar was loose, carious, and contained a septic pulp. The tooth and some necrosed bone were removed, but the discharge became more profuse in spite of local and general treatment. At the expiration of about five weeks the inner margin of the alveolus which had separated was removed. The necrotic process continued to spread. Some seven months subsequently in attempting to remove a loose fragment of bone the whole left half of the mandible including the ascending ramus was discovered loose and was removed through the mouth. The patient made rapid recovery and but little facial deformity resulted. The movement of the joint was perfectly normal and even during the separation of the sequestrum was fairly free, due to the fact that the disease stopped before it reached the articular cartilage. The necrosis seems to have been due to septic inflammation in connexion with the deciduous molars. The interesting features of the case seem to be the apparent freedom from general trouble from the constant swallowing of the discharge, the rapid and excellent recovery, and the removal without the aid of an external incision of so large a portion of the mandible.

CAMBRIDGE SUMMER SCHOOL OF MEDICINE.

THE success of this gathering in 1894 was so great that we understand it is in contemplation at Cambridge to renew the invitation to qualified medical men to visit the University. It is hoped that at about the end of June arrangements can be made at the laboratories to demonstrate to the visitors the latest advances in the medical sciences. The colleges are being approached in the hope that they will afford accommodation to a certain number of visitors as before at cost price. When the arrangements are complete due notice of them will be given.

THE LEGAL CONTROL OF PROSTITUTION IN THE UNITED STATES.

THE *Medical Record* of New York publishes a paper by Dr. S. Lustgarten of New York on the above subject. The paper was contributed to the Transactions of the International Conference for the Prevention of Syphilis and Venereal Diseases held in Brussels in September, 1899. The chief interest of the paper is in showing the almost complete absence of legislation in the United States to secure control over prostitution and the two great reasons for such absence. First, in the sovereignty of the individual states in dealing with such subjects for themselves and by themselves, and, secondly, the absence of any public feeling in the States on a large scale in favour of such legislation. There is only one instance in the history of the States of an attempt at legislation of this kind. The Missouri Legislature in 1872 enacted a law to regulate prostitution in the city of St. Louis. Though the law operated beneficially in the estimation of well-informed writers and physicians it only remained on the statute books of the State for about a year and it was repealed in dramatic style with popular demonstrations. Dr. Lustgarten points out that for any such legislation to be beneficial it must include all the states. Otherwise the effect is merely to drive prostitution to other states and cities.

THE SALE OF FOOD AND DRUGS ACT, 1900.

CIRCULARS similar to those issued some months ago by the Board of Agriculture in London have been issued by the Local Government Board in Edinburgh to the local authorities of Burghs in Scotland. It is pointed out that by Section 23 of the Act now in force all the powers and duties vested in or imposed upon the Secretary for Scotland in relation to the Sale of Food and Drugs Act are transferred to the Local Government Board in Edinburgh. The circulars contain much the same useful information as those which were issued by the Board of Agriculture in London and which were dealt with in an annotation in THE LANCET of Nov. 18th, 1899 (p. 1389). The better control over the manufacture and sale of margarine is the subject of an attached circular. The chief points to be noticed by the authorities who are entrusted with the carrying out of the purpose of the Act are as follows:—The power of the Board whether in Scotland or England of securing the execution and enforcement of the Act, the definition of food, provision of more stringent fines, the enforcement of Acts where negligence is evident, and the fact that i imperative on every local authority now to appoint a pu analyst without reference to a central authority.

THE NEW UNIVERSITY OF BIRMINGHAM.

THE charter and statutes for the government of new University of Birmingham have been laid on table of the House of Commons. Mr. Chamberlain is to the first Chancellor. The Principal, who is to be appoin by the Crown, is not yet nominated. Mr. Bertram Cogl Alan Windle, M.A., M.D., D.Sc., F.R.S., has b appointed the first Dean of the Faculty of Medici Certain interesting questions arise out of these appointme as showing that the University is at length a reali There is, for instance, the very interesting question, fr a medical point of view, as to a representative upon General Medical Council. In any case the medical p fession may congratulate itself upon the election of so tinguished a teacher as Dr. Windle to the responsible p which he holds.

WE understand that the President of the Board of Ag culture has appointed a Departmental Committee to inqu and report as to what regulations may be made by the Bo in regard to the standards of quality of milk and cream. difficulty in connexion with proceedings taken under Sale of Food and Drugs Act has been to differentiate exac between abnormal milk or milk which has been wate or from which cream has been abstracted. It is to hoped that the long-vexed question of what is a what is not genuine milk or cream may be decid by this committee by recommending a system of f standards. Public analysts in particular will welcome announcement of the appointment of this committee whi will consist of the following gentlemen:—Lord Wenlc (chairman), Mr. George Barham, Mr. George Cowan, Ma Patrick George Craigie, Mr. S. W. Farmer, Mr. Shir Murphy, Professor Thorpe, and Mr. J. Augustus Voelck Mr. Robert Henry Rew (of the Board of Agriculture), v serve as secretary to the committee.

THE Odontological Society of Great Britain is prepared receive applications for grants in aid of the furtherance scientific research in connexion with dentistry. For furt particulars application should be made to the Honor Secretary, Scientific Research Sub-committee, Odontologi Society, 40, Leicester-square, London, W.C.

THE subject for discussion at the annual clinical debate to be held by the Chelsea Clinical Society on March 13th and 20th is the Treatment of Rheumatism, with special reference to Prophylaxis and Cardiac Complications. The names of the speakers will be shortly announced.

MR. R. Clement Lucas has been appointed by the Treasurer and Governors of Guy's Hospital, on the unanimous recommendation of his colleagues, to the lectureship on Surgery in the Medical School, rendered vacant by the resignation of Mr. N. Davies-Colley.

NEWPORT AND MONMOUTHSHIRE INFIRMARY.—At the annual meeting in connexion with the Newport Workmen's Infirmary Fund held on Jan. 24th under the presidency of the mayor it was stated that £1027 had been collected during 1899, being an increase of £212 as compared with the preceding year.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

(Continued from p. 2[illegible].)

WE gave last week a brief outline of the final report of Lord Llandaff's Commission on the London Water-supply. The recommendations which the Commissioners gave were, it may be remembered, that the metropolitan water companies' undertakings should be purchased and placed under the control of a Water Board and that it was unadvisable that the purchase should be effected by the London County Council. In order to obtain a clear idea of the reasons which led the Commissioners to come to the conclusion that the undertakings should not be purchased by the London County Council we reproduce a map which was prepared for the Balfour Commission and which appeared in their report, and was also reproduced in the first of the articles on the London water-supply which appeared in THE LANCET.[1] A mere glance at this map shows how small a part the county of London (which is represented by a shaded area) occupies in the larger area included under the term "Water London" (which is defined in the map by a dark line). It will be noticed that the area of the New River extends to the north of Ware and that that of the Kent Company spreads southwards beyond Westerham, while to the east and west Water London spreads to a considerable distance beyond the county of London itself. The Royal Commission had to consider the interests of the inhabitants of the whole of this vast area nor could they with justice ignore the opinions of the outside areas for the sake of a limited part of the district, for the good of the whole of which they were asked to give their advice with regard to the future supply of water. One of the questions, therefore, which the Commissioners had to consider was whether the undertakings should be acquired and managed by one or by several authorities, and they had to take into account the opinions expressed by the metropolitan counties who insisted that their supply should be altogether severed from that of London, both with regard to supply and distribution of water, if it were decided that the county of London should purchase the water companies' undertakings The Commissioners therefore had to consider to what extent physical severance of the works and other property and sources of supply and the division thereof between different local authorities within the limits of supply were practicable and desirable. They found in the course of their inquiry that the area of supply of the metropolitan water companies included in the county of Middlesex alone 21 urban and rural district councils; that in the county of Surrey it included three boroughs and nine urban and rural district councils; that in the county of Essex it included one borough and 13 urban and rural district councils; that in Hertfordshire in included five urban and rural district councils; and that in Kent it included eight urban and rural district councils. It had not been suggested that it was desirable to divide the sources of supply and works of distribution between these 60 local authorities; that alternative therefore the Commissioners dismissed from serious consideration On the other hand, it had been suggested that severance and division of the sources of supply might be effected between the six metropolitan counties which were included in the water area. The only witness, however, who attempted to formulate any scheme for dividing the sources of supply between the six counties was Sir Alexander Binnie. Assuming that the London County Council were to purchase the undertakings of the water companies he proposed a plan for the division of the supplies between the counties of London and Surrey and between London and Middlesex In the case of Kent he suggested that the county of London should take those wells of the Kent Company which are in the county of London and buy in bulk from the county of Kent some undefined quantity of water produced by those wells of the Kent Company which are in the county of Kent and which the Commissioners say should primarily belong to that county. With regard to Hertfordshire the suggestion was that the county of London should buy and retain the existing sources of the New River and undertake not to draw any more water than is drawn at the present time or more than some quantity which might be afterwards agreed upon. With respect to the supplies at present given by the New River Company it was suggested by Sir Alexander Binnie that they should continue to be given by the county of London as a supplying authority, or that London should hand over to Hertfordshire a fixed quantity of water to be distributed by the authorities of that county. In the case of the county of Kent Sir Alexander Binnie did not offer any suggestion. The Commissioners report that the suggestions put forward by Sir Alexander Binnie negative the desirability and even the practicability of severing the sources of supply and works of distribution in the case of all the metropolitan counties. Sir Alexander said that as a water engineer he would not advise severance from an economical point of view in the administration of works and that the objections to severance and its cost would lead the outside authorities to take water in bulk from the county of London and that they should content themselves with distributing it in their own district. He gave it also as his opinion that should water be supplied in bulk from the county of London to the outlying authorities London, as the supplying authority, ought to be made responsible for giving an increased supply should it be necessary to do so in order to keep pace with the requirements of a growing population and that the county of London ought to be paid some small sum for working the business. On the other hand, if there were *complete division of the sources of supply* and the works of distribution the adjacent counties would in case of necessity have to provide themselves with new sources of supply as soon as the population had outgrown that which had been allotted to them in the partition. Sir Alexander Binnie had made no estimate as to the cost of the carrying out the work of partition. The Commissioners report that the scheme of partition in all its manifestations was too technical and complicated a matter for them to treat in detail and they therefore content themselves by pointing out as an example of the intricacy of any possible scheme the case of a suggested division of the works of supply between the counties of London and Surrey. In our report of the meetings of the Royal Commissioners the evidence on this subject was fully given, and here we need do no more than quote in the words of the Commissioners their brief *résumé* of the works which it would be necessary to carry out:—

> We must content ourselves with saying that the suggested division of works of supply and of distribution between the counties of London and Surrey would involve dividing reservoirs into two by embankments, leaving the outside county with only one main, and no alternative means of supply, dividing the engine power at different stations in some undefined way, with the consequence that the workmen of the two counties would have to use the same engine-house, with only one common steam-supply. Water intended for distribution in Surrey, and belonging to Surrey, would have to pass through reservoirs belonging to London, and pass out of the county of London again; mains used for distribution would have to be converted into pumping mains, and *vice versâ*; considerable works, such as reservoirs now laid out for the supply of several districts, would have to be applied to the use of one district; the workmen employed by London and Surrey respectively would have to work side by side and on the same premises, in filtering and sand washing operations, the division of the engines and mains at Hampton could only be effected by handing over to Surrey three times as much engine-power and four times as much main capacity as the needs of the county required.

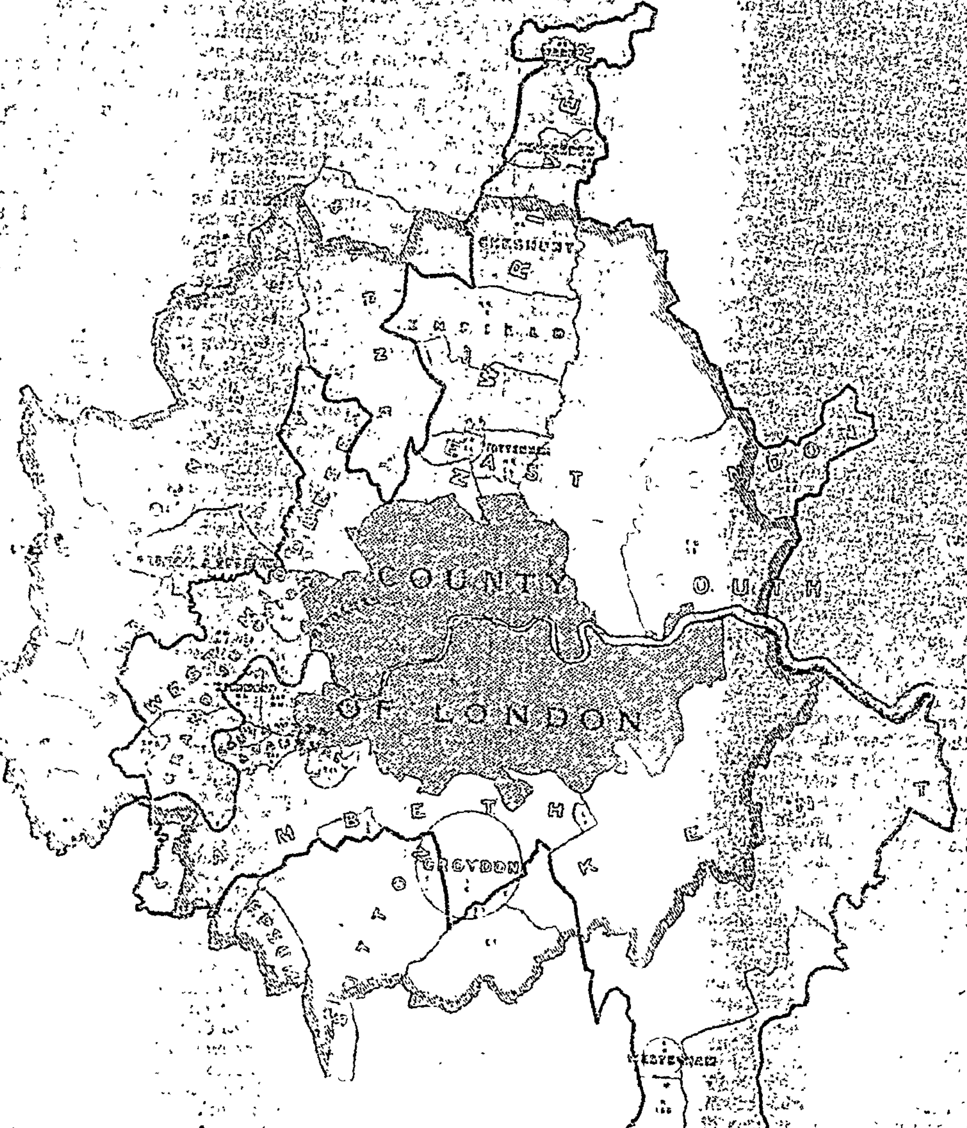
The Commissioners point out that Mr. Middleton gave it as his opinion that the present arrangements of the metropolitan water companies' undertakings were so intricate that practically it would be better to reconstruct the works altogether than to attempt to divide them, and he gave in detail the difficulties and inconveniences of dividing the pumping machinery, engines, boiler-power, and subsiding reservoirs at Molesey between the counties of London and Surrey, and the difficulty that would arise in apportioning filter-beds and the engines which pump the water. He also showed that there would be similar difficulties after the water had left the filter-beds, and in his opinion it would be better for Surrey to leave the present water undertakings to London and to supply themselves with water independently. The Commissioners recapitulate in some detail the evidence which was given on the difficulties of dividing the companies' present undertakings in such a way that the water should be divided between London and the outlying authorities. The evidence on which they dwell was reported at the time when it was given at the various sittings of the Commissioners,[2] and many of the facts were even then familiar to readers of THE LANCET, as they had already appeared in the articles which were given on the politan water-supply.[3] For example, the Com- ners point out that the intakes, service reservoirs, and filter-beds of the East London Company are all outside the county of London. If, therefore, London bought the water of the company and supplied Essex with water in bulk it would be necessary to bring all the filtered water from outside London into London and send it again to Essex through a number of mains on all of which meters would have to be placed, while London would have to construct fresh service reservoirs for that part of London which was to be supplied from the present East London Company's sources. The New River Company's undertaking presented similar difficulties with regard to severance. Half their reservoirs are outside the county of London, their mains cross and re-cross the boundary 38 times along seven miles of boundary, and there are in addition numerous crossings of the service mains and service pipes. In the case of severance in order to enable London to give a supply in bulk to the outside authority all these pipes would have to be metred, unless at great expense many of the mains were relaid, or new ones put down.

---

[1] THE LANCET, Feb 20th, 1897, p 5[illegible].

[2] [illegible]

Similar difficulties, the Commissioners point out, the undertakings of the other companies. fore, that the system of supply in bulk is not only inconvenient and expensive but it shuts out the supplying authority from prospective increase of income district of supply. The price of the water so would doubtless be fixed and if London were to supply bulk at a fixed price the ratepayers of London would themselves in a less satisfactory financial position than that which the eight present metropolitan present enjoy or in which a purchaser who took over the present system would possess if the administration did not require division. The Commissioners come to the conclusion that although severance of the works of supply and division of them between the councils of the six counties within the limits of supply is not actually impracticable it would be very difficult and highly undesirable. They report that the metropolitan counties appeared determined to insist on being altogether severed from London, both with regard to the supply of water and the distribution of it, should the county of London purchase the undertakings of the water companies. In the case of Middlesex the opinion frequently expressed by the Middlesex County Council was that



The Administrative County of London is represented by the shaded area. The black line defines "Water London," the area of the Metropolitan water-supply. The shaded line defines the Metropolitan and City Police area.

---

[3] THE LANCET Special Commission on the Metropolitan Water-upply, Feb. 20th, 1897, et seq.

scheme would be acceptable which did not provide for the independent control by Middlesex of the distribution of the supply for Middlesex and the absolute non-interference with Middlesex either as to rating or otherwise. The Surrey County Council, supported by the various urban and rural district councils and parish councils of the county which would be affected by the change, is opposed to any scheme that would put Surrey under the control of the London County Council, and the Surrey County Council has always insisted upon having the sources of supply as well as the distribution of water in its own hands should the present arrangements be changed. The Kent County Council desires that the Kent Company shall be left to exist in its present state and wishes that arrangement to be permanent. There is no desire to buy the undertaking, but should it be purchased by the London County Council Kent demands to purchase its share both of the sources of supply and means of distribution, and the county of Kent objects to the London County Council having any power at all in that county. The County Council of Essex agrees to the purchase of the metropolitan water companies by the London County Council only on the terms that Essex shall have the supply and distribution of water in its own county. The feeling of Essex was neither in favour of nor against municipalisation of water-supply, but there was a very strong feeling that the London County Council should not have any power of control of the water in Essex. The county of Hertfordshire thinks that the New River Company and the East London Company already abstract more water from the county than they are entitled to either by charter or by statute It opposes purchase by the London County Council because it thinks that that council would be inclined to abstract even more water than the present peccant companies. The county has no idea of buying the New River undertaking or any part of it. Very few supplies are given in the county by the New River Company.

The Commissioners attach great weight to the objections of the county authorities to being placed by purchase under the control of the London County Council in consequence of the large numerical proportion of the water-consuming population which is under the jurisdiction of those counties and not at present in any way under that of the London County Council. Even at the present time, the Commissioners point out, this population is between one-fifth and one-quarter of the whole population supplied by the water companies; it is increasing at a more rapid rate than the population of London proper; and if and when the population of Water London reaches 12,000,000 it is possible that the population of this outer ring, for which additional water may be wanted, may equal in number that of the administrative county of London. The Commissioners report that should the London County Council purchase the undertakings division of the works of supply must necessarily follow; this division is open to so much objection that it is practically inadmissible; therefore the London County Council should not be allowed to purchase the metropolitan water companies' undertakings.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary meeting of the Comitia was held on Jan. 26th, Dr. W. S. CHURCH, the President, being in the chair.

The following gentlemen having passed the required examination were admitted as Members:—Edwin Bramwell, M.B. Edin., Walter Langdon Brown, M.A., M.B. Cantab., Andrew Duncan, M.D. Lond. Charles Oliver Hawthorne, M.D. Glasg., Robert Jones, M.D. Lond., L.R.C.P., John MacLeod Hendrie MacLeod, M.A. St. And., M.D. Aberd., Clive Riviere, M.D. Lond., L.R.C.P., Alfred Ernest Russell, M.D. Lond., L.R.C.P., Alfred Walter Sikes, M.D. Lond., L.R.C.P., Lewis Albert Smith, M.B. Lond., L.R.C.P., and Ralph Harry Vincent, M.B. Durh., L.R.C.P. Licences to practise were granted to 112 gentlemen who had duly satisfied the examiners and Diplomas in Public Health were granted, conjointly with the Royal College of Surgeons of England, to 13 gentlemen.

The following communications were received:—1. From the Secretary of the Royal College of Surgeons of England (3), reporting certain proceedings of their Council. 2. From a Committee of the Local Government Board asking the College to appoint two representatives to give evidence on the question, How Far Certain Preservatives and Colouring Matters added to Food are Injurious to Health. The PRESIDENT suggested that Sir T. Lauder Brunton and Dr. G. Vivian Poore should be appointed and the proposal was adopted 3. From Mr. Davies-Colley, resigning his appointment as Examiner in Surgery to the College owing to ill-health. The PRESIDENT expressed the regret felt by the College in accepting this resignation.

The PRESIDENT announced that Professor Clifford Allbutt had been selected as Harveian Orator; Dr. Archibald Garrod as Bradshaw Lecturer; and Dr. John Sykes, medical officer of health of St. Pancras, as Milroy Lecturer.

Dr. P. Frank, Sir William R. Gowers, Dr. T. Barlow, and Dr. Sidney Coupland were elected Councillors in the room of Dr. A. E. Sansom, Dr. Mitchell Bruce, Dr. W. H. Allchin, and Dr. Frederick Taylor, who retire by rotation

Dr. Sidney Martin was elected a Member of the Laboratories Committee in the place of Dr. J. F. Payne.

On the motion of the Senior Censor (Dr. P. H. PYE SMITH), seconded by the Registrar (Dr. E. LIVEING), it was resolved that the following words be substituted for those in the By-law commencing "may declare such Fellow" to the end—viz.:—

> May declare such Fellow not to be a Fellow or a Member of the College, or such Member not to be a Member of the College, or such Licentiate not to be a Licentiate, for a limited period of time or altogether as the College shall determine, and such Fellow, Member, or Licentiate shall forfeit all the rights and privileges which he does or may enjoy as a Fellow or as a Member or as a Licentiate as the case may be, either for such limited period of time or altogether as the College shall determine; and his name shall be expunged from the list of Fellows or from the list of Members or from the list of Licentiates, as the case may be, either for such limited time *or altogether as the College shall determine.*

A report, dated Nov. 20th, from the Committee on the Nomenclature of Diarrhœa was received, in which it was recommended that the term "epidemic enteritis" should be used as a synonym for epidemic diarrhœa and that the College should urge the entire disuse as synonyms of epidemic diarrhœa in medical certificates of death of such terms as "gastro-enteritis," "muco-enteritis," or "gastric catarrh."—After a discussion, in which Dr. William Hunter, Dr. Donald MacAlister, Dr. J. F. W. Tatham, Dr. J. F. Payne, Dr. R. J. Lee, and the President took part, the report was adopted.

Reports were also received and adopted from the representative of the College on the General Medical Council (Sir Dyce Duckworth), from the Finance Committee, from the Committee of Management, and from the Laboratories Committee. The report from the Committee of Management included the syllabus for the Diploma in Public Health, Part I. and Part II.; the recognition of Cooke's School of Anatomy as a place of instruction in anatomy and physiology for candidates referred at the second examination; the recognition of the course of operative surgery at Cooke's School of Anatomy; and the recommendation that Cornell University should be added to the list of institutions recognised by the board at which the whole curriculum of professional study may be completed and where graduates in medicine are admissible to the final examination.

A list of books and other publications presented to the library during the past quarter was received and thanks were returned to the donors. Amongst the books were 23 medical works of the seventeenth and eighteenth centuries, presented by the Governor of the Bedford General Infirmary; a splendidly bound copy of "Cooper's Anatomy," sixteenth and seventeenth centuries, presented by Dr. Coates of Bath; an interesting MS. of the seventeenth century, containing a collection of "Remedies for the Universall Parts of the Body," presented by Dr. Poore; three old seventeenth-century medical works presented by Dr. Stevenson; and Sir Thomas Browne's "Christian Morals," presented by Dr. Osler.

THE YARROW CONVALESCENT HOME.—The trustees of the Yarrow Convalescent Home desire it to be made known among the medical profession that during the winter months accommodation is provided for a limited number of children requiring active treatment and a lengthened stay is granted when there is a prospect of a permanent benefit. This home has placed at the disposal of the Officers' Families Fund 30 beds for the reception of any convalescent children of officers who have either been killed or wounded in the present South African war.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Chelmsford and Maldon Rural Districts.—Dr. J. C. Thresh, in addition to holding the post of medical officer of health of the county of Essex, is also medical officer of health of the above two districts, and in this latter capacity he has set an excellent example by the prompt issue of his annual reports for the year 1899. They are the first which we have received. In both these districts there is apparently some discontent with the building by-laws, which are regarded by certain persons as being too stringent, and in the Chelmsford district a committee has been appointed to inquire into the matter. The present by-laws, it is alleged, inhibit or totally prevent the erection of agricultural labourers' cottages. As regards the question of the housing of the working classes in the Maldon Rural District Dr. Thresh thinks the only remedy to be the adoption of Part III. of the Housing of the Working Classes Act and he furnishes figures which will, we trust, tempt the council to try the experiment. Dr. Thresh, however, expresses the opinion that the Act referred to requires simplification in the direction of affording facilities for acquiring money more cheaply and extending its repayment over 50 years. It is useless, he observes, to condemn houses in cases where the displaced tenants have no other houses to which they can betake themselves. In Essex the movements of "holiday children" from London have to be carefully watched, and Dr. Thresh reports that he was able last year to prevent children being sent to a village where scarlet fever was prevalent. He suggests that associations sending children into the country should previously notify their intentions to the medical officer of health of the district to which the children are to be sent. An inquiry has recently been made in the Chelmsford and Maldon districts into the distribution and behaviour of cancer since 1871. Dr. Thresh placed his books at the disposal of Dr. G. M. Scott of Witham who undertook the investigation. The report is, Dr. Thresh tells us, shortly to be published in full, but he furnishes us with the following table and the conclusions at which Dr. Scott has arrived.

Deaths from Cancer per 1000 of the Population.

—	1871-80		1881-90		1891-1900	
	Total deaths.	Deaths per 1000 population.	Total deaths.	Deaths per 1000 population.	Total deaths.	Deaths per 1000 population.
Males	93	5·2	135	4·7	204	7·0
Females	181	6·4	220	7·7	244	8·4
Total...	274	4·8	355	6·2	448	7·7

1. During the earlier part of the period under consideration the death certification was wanting in detail.
2. The increase in the number of deaths certified as being due to cancer is real in part, but is chiefly due to greater accuracy in diagnosis.
3. On the average there are proportionately fewer cancer deaths in Essex than in England as a whole; fewer in the area under consideration than in the county of Essex; and fewer in the Maldon than in the Chelmsford Union.
4. A low mortality may exist under the most diverse physical and sanitary conditions.
5. A low cancer rate exists near those parts which are characterised by muddy foreshore and salt-water creeks.
6. In some parts having a high mortality from cancer the subsoil water lies near the surface. (This condition seems to be more common than any other, but there is one very notable exception—Tollesbury.)
7. In those parts which lie on the banks of rivers there is no special prevalence of the disease.

Another table furnishes the rates in the several parishes of the districts, and we look forward to the full report to tell us in what manner the age distribution of the population has had an influence on the different rates.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6790 births and 5025 deaths were registered during the week ending Jan. 27th. The annual rate of mortality in these towns, which had been 30·9, 29·1, and 24·9 per 1000 in the three preceding weeks, further declined to 22·6 last week. In London the rate was 22·2 per 1000, while it averaged 22·8 in the 32 provincial towns. The lowest death-rates in these towns were 8·9 in Cardiff, 10·7 in Croydon, 14·7 in Birkenhead, and 15·3 in Swansea; the highest rates were 29·5 in Liverpool, 29·7 in Wolverhampton, 30·1 in Sunderland, and 30·7 in Preston. The 5025 deaths in these towns included 428 which were referred to the principal zymotic diseases, against numbers decreasing from 578 to 443 in the five preceding weeks; of these 123 resulted from measles, 99 from whooping-cough, 94 from diphtheria, 43 from diarrhœa, 35 from "fever" (principally enteric), 33 from scarlet fever, and one from small-pox. No death from any of these diseases occurred in Gateshead; in the other towns they caused the lowest death-rates in Croydon, Cardiff, Birkenhead, and Newcastle, and the highest rates in Salford, Burnley, Preston, and Sheffield. The greatest mortality from measles occurred in West Ham, Salford, Preston, Bradford, and Hull; from scarlet fever in Burnley and Preston; and from whooping-cough in Birmingham, Liverpool, Salford, Preston, and Leeds. The mortality from "fever" showed no marked excess in any of the large towns. The 94 deaths from diphtheria included 37 in London, 26 in Sheffield, four in Leeds, and four in Liverpool. One fatal case of small-pox was registered last week in Hull, but not one in any other of the 33 large towns. There were 24 cases of small-pox under treatment in the Metropolitan Asylums Hospitals on Saturday last, Jan. 27th, against numbers increasing from five to 21 on the five preceding Saturdays; four new cases were admitted during the week, against one, 10, and five in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2287, against numbers decreasing from 3578 to 2441 at the end of the 10 preceding weeks; 190 new cases were admitted during the week, against 186, 180, and 207 in the three preceding weeks. Influenza was certified as the primary cause of 152 deaths in London last week. The deaths referred to diseases of the respiratory organs in London, which had been 1221, 994, and 728 in the three preceding weeks, further declined to 490 last week, and were 70 below the corrected average. The causes of 62, or 1·2 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Newcastle, and in 11 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Sheffield, Hull, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·0 and 23·3 per 1000 in the two preceding weeks, further rose to 23·4 during the week ending Jan. 27th, and was 0·8 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 15·2 in Leith and 15·9 in Paisley to 26·7 in Dundee and 27·6 in Aberdeen. The 723 deaths in these towns included 32 which were referred to measles, 23 to diarrhœa, eight to scarlet fever, eight to whooping-cough, seven to diphtheria, and three to "fever." In all 81 deaths resulted from these principal zymotic diseases, against 64, 65, and 61 in the three preceding weeks. These 81 deaths were equal to an annual rate of 2·6 per 1000, which was 0·7 above the mean rate last week from the same diseases in the 33 large English towns. The 32 fatal cases of measles corresponded with the number in the preceding week, and included 19 in Glasgow, eight in Dundee, two in Greenock, and two in Perth. The deaths from diarrhœa, which had declined from 17 to seven in the four preceding weeks, rose again last week to 23, of which 13 occurred in Glasgow, three in Dundee, and three in Aberdeen. The fatal cases of scarlet fever, which had been four and eight in the two preceding weeks, were again eight last week, and included six in Glasgow. Of the eight deaths from whooping-cough, which were equal to the number registered in the preceding week, five occurred in Glasgow and two in Edinburgh. The fatal cases of diphtheria, which had been three, five, and seven in the three preceding weeks, numbered seven last week, and included three in Glasgow and two in Dundee. The three deaths from "fever," all of which were registered in Glasgow, showed a decline of three from the number in each of the two preceding weeks. The deaths from diseases of the respiratory organs in these towns, which had declined from 253 to 198 in the four preceding weeks, further decreased to 172 last week, but were 11 above the number in the corresponding period of last year. The causes of 20, or nearly 3 per cent, of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death rate in Dublin, which had been 50 3, 49 4, and 44 0 per 1000 in the three preceding weeks, further declined to 38 6 during the week ending Jan. 27th. During the past four weeks the death-rate in the city has averaged 45 6 per 1000, the rate during the same period being 29 9 in London and 22 2 in Edinburgh. The 259 deaths registered in Dublin during the week under notice were 36 below the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 31 and 22 in the two preceding weeks; of these five resulted from measles, three from whooping-cough, one from diphtheria, one from "fever," and not one either from small-pox, from scarlet fever, or from diarrhœa. These 10 deaths were equal to an annual rate of 1 5 per 1000, the zymotic death-rates during the same period being 1 8 in London and 0 9 in Edinburgh. The fatal cases of measles, which had been 18 and nine in the two preceding weeks, further declined last week to five. The deaths referred to whooping-cough, which had been one and three in the two preceding weeks, were again three last week. The mortality both from diphtheria and from "fever" showed a decline from that recorded in recent weeks. The 259 deaths in Dublin last week included 32 of infants under one year of age and 91 of persons aged upwards of 60 years; the deaths of infants exceeded the number in the preceding week, while those of elderly persons showed a decline. Seven inquest cases and two deaths from violence were registered, and 91, or more than a third, of the deaths occurred in public institutions. The causes of 15, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: — Staff-Surgeon: James L. Smith to the *Ocean*. Surgeons: Edward C Sawdy to the *Ocean*, William Hackett to the *Pique*; Thomas D. Halahan to Plymouth Hospital; Kenneth H. Jones to the *Pembroke*, Henry E. Raper to the *Repulse*, and James M. G. Swainson to the *Trafalgar*.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel C. Healy, retired pay, proceeds to Cork for duty. Captain P Evans has arrived at Portsmouth for duty. Major H B. Mathias is selected for the charge of the Mosely Hospital for South Africa. Lieutenant-Colonel E. J. Fairland, A M.S, retired pay, joins the Home District for temporary duty as a Recruiting Medical Officer, and Majors D. Stiell and R. H. Clement join at Woolwich.

THE CITY OF LONDON IMPERIAL VOLUNTEERS.

Surgeon-Captain R. R. Sleman, 20th Middlesex Volunteer Rifle Corps, to be Medical Officer, with the temporary rank of Captain. Surgeon-Captain A. Thorne, 2nd Middlesex Volunteer Artillery, to be Medical Officer, with the temporary rank of Captain. Surgeon-Captain E. V. St. V. Ryan, 16th Middlesex Volunteer Rifle Corps, to be Medical Officer, with the temporary rank of Captain.

VOLUNTEER CORPS.

Artillery: 1st Cheshire and Carnarvonshire: Surgeon-Lieutenant W. G. Owen resigns his commission. *Rifle*: 1st Volunteer Battalion the Queen's Own (Royal West Surrey Regiment): Thomas Francis Devane, to be Surgeon-Lieutenant. 1st Cadet Battalion the Queen's Royal West Surrey Regiment: A. C. Ellman to be Acting Surgeon. 1st (Brecknockshire) Volunteer Battalion the South Wales Borderers: Hubert Williams to be Surgeon-Lieutenant. 1st Tower Hamlets: Surgeon-Captain J. P. Simpson resigns his commission.

TRANSVAAL WAR NOTES.

It is expected that the *personnel* of the Imperial Yeomanry Hospital will start next week or early the week following for South Africa. Huts for 200 beds, it is hoped, will be ready when the hospital and staff arrive at Cape Town.

Mr. A. Mosely, a Bristolian living in London, has presented a field hospital, which is to be called the Princess Christian Hospital, to the War Office. It will contain 100 beds and be stationed in the neighbourhood of Cape Town. Major H. B. Mathias, R A.M C, will be at the head of the five surgeons employed, and Mr. J. Paul Bush will be placed in charge of the civil section. Nurse Lawrence, daughter of Judge Lawrence of Cape Town, with four sisters, will take over the nursing department. Six non-commissioned officers and 24 ordnance men will complete the staff.

Mr. L. Echenard-Neuschwander has placed at the disposal of convalescent English officers returning from South Africa four rooms free of expense at the Grand Hôtel du Louvre et de la Paix at Marseilles. This offer has received the approval of the War Office.

Captain C. Dalton, R A M.C, was severely wounded at the operations at Chieveley on Jan. 23rd.

In a despatch from Modder river dated Dec. 1st referring to the operations there on Nov 28th Lord Methuen says:—"Again I call attention to the splendid hospital arrangements, for at 4.45 P M. on the day after the fight all my wounded were on their way to Cape Town. I am glad to have been slightly wounded, because in no other way could I have learnt the care taken of the wounded, and there was nothing officer or private soldier required that was not provided at once, and the medical officers never tired in their endeavour to alleviate suffering."

THE ROYAL ARMY MEDICAL CORPS IN EGYPT.

The *London Gazette* of Jan. 30th contains a despatch, with enclosures, from Lord Kitchener of Khartoum to the Under-Secretary of State for War, London. In an enclosure from Colonel Sir F. R. Wingate, commanding troops on the White Nile, dated Fachi Shoya, Nov. 25th, 1899, Colonel Wingate says: "Lieutenant Stallard (Royal Army Medical Corps) was in charge of the medical arrangements, and was ably assisted by Lieutenant Nickerson (Royal Army Medical Corps) These officers did all that was possible, not only to alleviate the sufferings of our wounded, but were also indefatigable in attending to the Dervish wounded, large numbers of whom passed through their hands" Lord Kitchener in his despatch says, "I freely endorse Colonel Wingate's remarks on the good services of the officers and men he has mentioned."

MALARIA AND BLOOD PARASITES.

In the *Archives de Medecine Navale* for November, 1899, Dr. H. Gros has a long and exhaustive review of Dr. Hans Ziemann's work on blood parasites in malaria.[1] "Although we think it is our duty to recommend the perusal of this *brochure* to all who take an interest in the highly important question of impaludism," says the reviewer in his exordium, "we shall nevertheless give a very complete *résumé* of M. Hans Ziemann's work. In it the author expounds the results of his own researches, which refer to 254 cases of malaria observed in Germany, in Italy, and under the tropics. The amount of research hereby indicated is most creditable and if we feel bound to differ with some of the conclusions arrived at by the author it is because they are often opposed to those of the Italian observers and also to those of M. Laveran, whose competence in the matter is indisputable." Dr. Ziemann has divided his subject into 17 sections, as follows: 1. A brief historical sketch in which the views of Golgi, Mannaberg, and the Italian school are given. 2. Classification of the malarial parasites. Dr. Ziemann accepts the following varieties: (*a*) the parasites of benign quartan ague; (*b*) of benign tertian ague; (*c*) of quotidian ague, malignant tertian and perhaps quartan, and irregular, capable of producing crescentic bodies. 3. General morphology and biology of the malarial parasites. 4. The parasite of quartan ague. 5. The parasites of tertian ague. 6. The parasites of æstivo-autumnal fever (pernicious fever of the tropics). 7. Sterile forms. 8. The clinical importance of searching for the parasites in tropical fevers. 9. The effects of various conditions and substances on malarial parasites. 10. Life of the parasites outside the human *body and modes of entry therein*. 11. Incubation. 12. The place in the animal kingdom occupied by the malarial parasites. 13. Researches regarding blood parasites in the cattle fever of Texas. 14. Parasites in the blood of birds. 15. Blood parasites in the owl (*Athene noctua*). 16. *Parasites in cold-blooded animals*. 17. Denying the existence of cytamœba bacterifera of Labbé, which the author believes to be an ordinary bacterium. Dr. Ziemann concludes with a description of the methods of colouration employed by him, and also gives various hints as to the best way of obtaining fine preparations. His work is well illustrated with engravings and photographic reproductions.

[1] Ueber Malaria und andere Blutparasiten, nebst Anhang, eine wirksame Methode der Chromatin und Entfarbung Fischer, Jena, 1898

ARMY MEDICAL SCHOOL, NETLEY.

The seventy-ninth session of the Army Medical School, Netley, was brought to a close on Jan. 30th. In consequence of the war in South Africa there was no public distribution of prizes. It will be remembered that the officers of the Royal Army Medical Corps passed out of the school in two batches during the months of November and December. Most of them are now in South Africa.

INDIAN MEDICAL SERVICE.

The following is the list of surgeons on probation who were successful at both the London and Netley examinations, Jan. 30th, 1900. The prizes are awarded for marks gained in the special subjects taught at the Army Medical School. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley and the combined numbers are accordingly shown in the list which follows.

	Marks.		Marks.
*A. C. MacGilchrist ...	6063	T. G. N. Stokes	4694
J. W. D. Megaw	5369	H. M. Mackenzie	4686
†E. O. Thurston	5224	M. H. Thornely	4620
G. Browse	4996	F. V. O. Beit	4473
C. M. Goodbody	4991	W. O'S. Murphy	4305
R. Steen	4970	M. Corry	4173
F. F. Elwes	4965	C. C. Murison	4097
J. L. MacInnes	4882	H. A. Williams	3963
E. A. C. Matthews... ...	4851	W. C. Long	3954
‡L. P. Stephen...	4845	G. C. Beamish...	3743
L. Gilbert	4813		

* Gained the Herbert Prize of £20, the Martin Memorial Medal, the Parkes Memorial Medal, the Second Montefiore Prize in Military Surgery, the Pathology Prize presented by the Director-General, A.M.S., and the Maclean Prize for Clinical and Ward Work.

† Gained the First Montefiore Prize of 20 guineas and the Bronze Medal in Military Surgery.

‡ Gained the de Chaumont Prize in Hygiene.

The following gentlemen obtained honourable mention in the subjoined departments:—Military Surgery: Mr. R. Steen, Mr. E. A. C. Matthews, and Mr. F. F. Elwes. Military and Tropical Medicine: Mr. H. M. Mackenzie, Mr. J. W. D. Megaw, and Mr. L. P. Stephen. Military Hygiene: Mr. T. G. N. Stokes, and Mr. H. M. Mackenzie. Pathology: Mr. E. O. Thurston and Mr. J. W. D. Megaw.

ROYAL ARMY MEDICAL CORPS FUND.

Since we called attention to the starting of this fund last week we learn that already a good many subscriptions have been received and many additional ladies have joined the committee, amongst whom we may mention Lady McGregor, Lady Burdon Sanderson, Mrs. Godley, Mrs. Butlin, Mrs. Berkeley Hill, Mrs. Meredith, Lady (Michael) Foster, Lady (Russell) Reynolds, Lady (Georgiana) Curzon, Lady Kennedy, Lady Hanbury, Mrs. Willett, Mrs. Buzzard, Mrs. Bradford, Mrs. Arbuthnot Lane, Mrs. Field, Mrs. Lauriston Shaw, Mrs. R. C. Lucas, and Mrs. Davies-Colley. The first meeting of the committee will be held on Monday afternoon next at 5 o'clock. Lady Duckworth has kindly consented to receive the meeting at her house, No. 11, Grafton-street, Piccadilly. An executive committee will be formed and the progress of the Fund will be reported. We understand that arrangements have been made through the Army Medical Department for the immediate despatch of a number of flannel shirts which have been already sent in. We hope next week to publish a full list of the committee and of the subscriptions. We may again mention the name and address of the honorary secretary—Miss Maxwell Muller, 100, Victoria-street, S.W.

DEATHS IN THE SERVICES.

Surgeon-Major Alexander Charles Archibald Alexande of Boydstone (1st Coldstream Guards) on the 23rd of las month. After qualifying he obtained a commission in th 3rd Battalion of the Royal Scots Fusiliers and served later i the 3rd Battalion, Coldstream Guards, which accompanied in the Suakim Expedition in 1885, and present at the engagements at Hasheen, at that near Tofrek and at the destruction of Temai (medal with clasp Khedive's star). Last year he returned from Gibraltar o sick leave, having had a slight sunstroke, from which unfortunately he did not entirely recover, so that to his great he was unable to accompany his regiment on the presen South African campaign.

THE LEGION OF HONOUR.

By virtue of a Presidential decree dated Dec. 25th, 1899 the dignity of knighthood in the Legion of Honour has bee conferred upon Dr. Finot, an officer of the French militar medical service. The *Journal Officiel* announces the distinction in the following terms:—

> Finot (Charles Jules Gabriel), Surgeon-Major of the Second Clas in the 15th Regiment of Artillery; 12 years' service, two campaign (Soudan). In the various engagements undertaken by the Sikass Column M. Finot constantly marched with the leading detachments exposing himself as much as the combatants and affording immediat aid to the men who were wounded by poisoned arrows.

LEAN'S ROYAL NAVY LIST.

No one who desires to know anything about the Roya Navy can afford to neglect this excellent publication, th eighty-ninth number of which lies before us. Here can b found the records of war and meritorious services of th officers of the Royal Navy, the Royal Marines, and Roya Naval Reserve, as well as a mass of information relating t ships and their war services. The publishers are Messrs Witherby and Co, 326, High Holborn, and 4, Newman's court, Cornhill.

COMPULSORY HOME SERVICE IN THE MILITIA.

We would call attention to a circular letter issued by Lor Wemyss on this subject in connexion with the propose application of the militia ballot. The letter is both interesting and useful in that it affords brief summary statements of the opinions that have been expressed by variou authorities on a subject of great importance and one which i attracting a good deal of attention at the present time.

THE WAR IN SOUTH AFRICA.

THE present time is one of depression and anxiety. A man who can make and enjoy a hearty breakfast after glancing at his morning paper requires to have a keen and vigorous appetite, and those who do not possess it or who are at all out of health will do well to defer the perusal of their newspaper until they have breakfasted. To sum up the situation briefly and to go to the root of the matter, our force in South Africa is not strong enough for the work which it has to do; our troops are usually outnumbered, the natural obstacles to be overcome are exceptionally difficult, and there are not any points at all capable of being defended of which the Boers have not in advance taken all possible advantage by strengthening them with entrenchments and every other artificial means in their power. The nation must be content to wait until a strong force can be organised and concentrated for the invasion of the enemy's territories with a definite end in view, which should, at any rate, have the effect of drawing off the Boer troops from their present positions. Meanwhile there is no wavering in the determination of the nation or the Government to prosecute the war to a successful issue, and a noteworthy illustration of the way in which all classes of society are responding to the national call was to be seen the other day at St George's Barracks, where a large number of well-connected young fellows had enrolled themselves as troopers in a corps of Yeomanry Infantry.

It is recognised on all sides that the Royal Army Medical Corps is doing splendid work in South Africa. The first official despatches from the seat of war, in which the generals give an account of their battles, have been received and published in the *London Gazette*. They are forwarded by Sir Redvers Buller and include reports from Lieutenant-General White and Lord Methuen and their subordinate officers, and treat of the actions at Glencoe, Elandslaagte, Rietfontein, Willow Grange, Belmont, Enslin, Modder river, and Colenso. These despatches furnish strong testimony to the grand character of the work that is being done by the medical officers, as may be seen by the following extracts. Lord Methuen reports:—

> I again draw attention to the exceptional organising power of Colonel Townsend at Swink's Pan at 11 30 P M I was informed that owing to all the ambulances having been used for taking the wounded to the train at Belmont I had scarcely a field hospital mounted officer, only three ambulances, and three stretchers. I knew I had to fight next morning so got together 60 blankets in order to carry wounded with help of rifles. I also sent to Colonel Townsend to make arrangements for wounded by 3.0 A.M, a messenger having to ride seven miles to him. He met me on the field with full supply of ambulances and I never saw anything more of him or the wounded because he had a train ready for them between Gras Pan and Belmont. His only complaint is that there is not much of his mules left, an observation which applies equally to men and animals

In a despatch descriptive of the operations at Modder river attention is called to Captain S G Moores, R A.M C., who, although wounded in the hand, said nothing but continued his duties. And Lord Methuen concludes this despatch with the following:—

> Again I call attention to the splendid hospital arrangements, for at 4 45 P.M. on the day after the fight all my wounded were on their way to Cape Town.
>
> I am glad to have been slightly wounded because in no other way could I have learnt the care taken of the wounded, and there was nothing officer or private soldier required that was not provided at once, and the medical officers never tired in their endeavour to alleviate suffering

These reports may be taken as samples of the general purport; they are eminently satisfactory and the officers of the Royal Army Medical Corps are to be sincerely congratulated. The army medical system in the field has been well thought out and organised and has been adopted after ample experience of its adaptation to the objects in view.

Reuter's Agency has been authorised by Lord Roberts to state that he has made a most careful inspection of all the hospitals at Cape Town and is perfectly satisfied that everything is done that can be done or that medical skill can suggest for the benefit and comfort of the sick and wounded. At the time of his visit there was some question of asking for additional nurses, but he found that the request in the sense which he had conveyed had already been anticipated by the home authorities, who cabled that they were sending as many nurses as he considered necessary to meet all possible requirements of the troops.

FATAL INJURIES WITHOUT APPARENT LESION.

Mr. S Osborn, F.R.C S Eng., chief surgeon to the Metropolitan Corps of the St John Ambulance Brigade, sends us the following interesting communication.—

Whilst volunteering as a surgeon amongst the wounded Greeks in the late Turco Greek war the following cases of fatal injuries without visible lesion presented the greatest interest. The ship *Albania* having been handed over to me I arranged it for the purposes of a hospital ship and proceeded to Volo with the idea of clearing the station hospitals situated there and leaving them ready for any further cases that might be brought down from the front The battle of Velestino taking place on my arrival and the town of Volo being subsequently occupied by the Turks necessitated not only my carrying out the above project but also removing, in addition, those of the wounded who had been brought direct from the battle field, and it was amongst the latter that these cases were found to which I desire to draw attention. There were three in all. One patient died on his way to the ship and was not taken on board and the other two patients died in a few hours and before the ship reached the Piræus. It is much to be regretted that on account of the amount of work and limited space at disposal no operation was attempted or post mortem examination performed. The symptoms were intense pain in the abdomen, generally referred to the pit of the stomach, accompanied by all the signs of shock and attended with constant retching The urine was drawn off and was quite natural. There was no external wound of any description, not even any bruising. The patients were kept under observation and under the influence of opium with the intention of being subjected to operation as soon as circumstances would permit, but which the fatal termination prevented.

What were these cases? We know the serious effect of buffer accidents, also of blows delivered "below the belt," to use fighting parlance, and also of what are called "wind
contusions" and

(NOTES FROM SIR WILLIAM MACCORMAC)

(*Continued from p 158*)

Durban, Dec 28th, 1899.—This morning I visited two of the hospital ships—viz, the *Lismore Castle* and the *Nubia*. The *Lismore Castle* was originally chartered by the Government from the Castle Line as an ordinary transport ship for troops. A sudden order having arrived that another hospital ship was to be equipped at once to supplement the *Spartan* (the first hospital ship fitted up at home), this vessel was chosen. She was handed over to the Admiralty on a Monday; two days were more or less occupied in coaling, and in spite of this the vessel was equipped and actually received sick on the Saturday, four and a half actual working days having been sufficient, under the management of Captain Holland, Indian Marine, and Major McCormack, R A.M.C, for the whole transformation. When the fittings of this ship as she now stands are compared with her previous accommodation as a troopship it is obvious that the quickness and method with which the work was completed reflect the greatest credit on all concerned. The Admiralty carpenters were ably assisted by civilians from Durban. The ship is at present under the medical command of Civil Surgeon Brodie, no Royal Army Medical Corps officer being available He is assisted by three other civil surgeons and has under his command the following staff one army nursing sister, four civilian nurses, 30 civilian male medical attendants, two qualified civilian dispensers, and one sergeant and nine men of the King's Royal Rifle Corps (to be used as fatigue men, guards, &c.)

The ship is noted as being particularly steady at sea Her tonnage is 4000 and she can provide for 250 sick, including convalescents. On the main deck are situated an officers' ward, an orderly room, an operating theatre, 15 convalescent officers' cabins, a disinfecting bath-room for linen, &c, three officers' bath-rooms, two water-closets, the mortuary, a dining saloon, a bar, &c. The officers' ward is situated in the stern of the ship It is a well-ventilated and comfortable cabin, running from side to side of the vessel, thus allowing of a free current of air. This ventilation is assisted by an electric air fan which materially helps to circulate the air. There are four beds in the ward, consisting of cots which can be allowed to swing or be made fast at will. Each cot is provided with mosquito curtains and can be separated from its neighbours by ordinary canvas curtains, forming a separate cubicle for each patient The ward is also provided with a kettle which can be heated very quickly by electricity. There is an ample supply of flowers and easy chairs, which are supplied both for the officers' wards and the men's wards by the ladies of Durban and by the Castle Company. This ward is lighted—as is, indeed, the whole of the ship—by electricity. The operating room consists of a specially constructed cabin, painted inside with white enamel, and the floor is covered with oil cloth. It is provided with a very serviceable operating table, which was purchased locally, an electric heated steriliser, moveable electric lanterns, and jars of antiseptic fluid, and it makes an airy, well lighted, and suitable room for the purpose. The [illegible] consists of 15 of capable of ly double-berthed passenger cabins, each labeled logy and lvalescent officer," and of these cabins three are of quart-hed and can accommodate two officers each. parasitortuary is situated in a cabin on deck in a far tropi. and is provided with a lead-covered table, &c. seardining-saloon is the ordinary saloon and is occupied by off medical officers, ships' officers, and nurses. The bar is poked after by the ship's steward, who is daily indented upon for the liquor required for the wards. The lower deck is divided into four wards, lettered respectively A, B, C, and D. A Ward is situated in the fore part of the ship and can be occupied by 150 convalescent men, who sleep in hammocks. B Ward contains 56 beds, C Ward 22 beds, and D Ward 21 beds. All of these wards run from side to side of the ship. The whole of the original inside of the ship's sides is covered by a wainscoting painted white. Two electric fans in each ward afford great comfort, and B Ward, being specially large, has four fans. The beds are all fixed, each one being provided with a hanging rope from the deck above, so that the patient may pull himself up in bed. There are easy chairs, flowers, books, handfans, and so on, to add to the comfort of the patients. In the fore part of A Ward is a bath-room supplied with fresh water and salt water, a pantry, a linen locker, and a disinfecting bath. This also is lighted by electricity. Two specially constructed lifts are used to convey the serious cases from the main deck and upper deck to the lower deck, the stretcher being placed upon the lift which is lowered by hand pulleys. Instead of the ordinary ship's ladders, long wide stairways with a very easy gradient have been fixed up, so that the men may reach the main and promenade decks without difficulty or fear of accident. The sick attendants are accommodated below A Ward, on the orlop deck. The main promenade deck has been given over to the convalescent patients and the bridge deck is reserved for the officers, who also have the use of the ship's smoking-room on this deck. Sick warrant officers are provided for in suitable ship's passenger cabins situated near D Ward on the lower deck. The whole ship outside was re-painted white and a large red Geneva cross has been added amidships. The Admiralty spent £1600 upon her re-construction, and in addition numerous articles have been added by the Donald Currie Line and by the ladies of Durban.

Having inspected the *Lismore Castle* we next visited the Peninsular and Oriental Company's ship *Nubia* lying close by. This ship had also been in use as a troopship until Dec. 26th, when orders were received to convert her into a third hospital ship, to be ready for occupation on Jan. 5th. At present she is in the hands of the workmen and is rapidly losing all internal recognition as a passenger ship. She is large and well ventilated, is painted white within and without, and is being fitted up on exactly the same lines as the *Lismore Castle*. Her medical staff has not yet been appointed. It is hoped that an officer of the Royal Army Medical Corps may be found available to take command, but the short-handedness of this corps at present with the large army at the front makes it probable that the vessel will be managed by civilians under the supervision of the principal medical officer of the Natal Field Force.

The whole of the inside of the bulwarks of the vessel are being wainscoted in the same manner as the other ships. The same electric air-fans and hot-water kettles, baths, water-closets, dispensary, &c., will be fitted up as in the other ships, and the general arrangements and distribution will be according to the following plan. The officers' ward will contain 10 cots and the officers' convalescent cabins 27 cots. The men's wards will be lettered respectively A, B, C, D, E, F, and G. A Ward will contain 100 cots (60 swinging and 40 fixed), B Ward 28 fixed cots, C Ward 28 fixed cots, D Ward 200 hammocks for convalescents, E Ward 30 fixed cots, F Ward 24 fixed cots, and G Ward 25 fixed cots, providing a total accommodation for 472 sick and convalescent patients. Each ward will be supplied with three electric fans, an electric kettle, a pantry, two baths, and from three to five water-closets. There will also be an antiseptic receptacle in each ward. The upper decks are very commodious and will be used for exercise as in the other ships.

On considering the most extensive surgical and medical work carried on in connexion with the Natal Field Force and the immense quantity of appliances and drugs which are being consumed by the field hospitals, bearer companies, regimental medical staff, stationary field hospitals, large hospitals on the lines of communications, hospital trains, and hospital ships—the arrangement and efficiency of which I have personally tested and described—the presents itself as to the sources of supply of all the bandages, drugs, splints, instruments, &c., whose renewal, especially after an engagement, becomes such an imperative matter. In order to satisfy myself upon these points and to the description of the medical arrangements in connexion with Natal I visited Major Mc Cormack, R.A.M.C., who is in sole charge of the Base Medical Stores Depôt situated in Durban.

The base depôt has been established in the goods shed of the railway station at Durban which has been kindly placed at the disposal of the Royal Army Medical Corps by Mr. D. Hunter, C.M.G., the general manager of the Natal Government Railway. This position was selected by Major Mc Cormack because (1) it is in direct rail communication with the wharf whence supplies arriving by steamer can immediately be run on trucks direct to the shed; (2) shed is practically on the departure platform and an arrangement having been made for the transmission of all medical supplies by mail train or passenger train no time is lost in their dispatch, and medical officers at the hospitals can thus receive their supplies a few hours after the dispatch of the wire demanding them; (3) it is within a few yards of the post and telegraph offices and is in immediate touch with the railway officials, who are doing everything in their power to accelerate the delivery of the stores as required; (4) electric light is also available being easily carried into this shed, so that work may be carried on by night, which is often necessary, as well as day; and (5) the shed is also very dry and safe. The supplies have all been forwarded from England, but in case of any unforeseen call upon his resources Mc Cormack has obtained lists and prices from all the chemists of Durban of all that can be purchased locally in case of need. He is also in direct communication by cable with the Director-General of the Army Medical Service, so that a continuance of the British supplies is assured with the smallest possible delay.

In order that the medical units actually engaged in the field may be able to replenish their supplies at the shortest notice a branch of this base depôt in the shape of an advance medical store train has been organised. This train consists of three large railway goods trucks. Accommodation is provided for a lieutenant and quartermaster (in charge), one sergeant, and two men, who live continuously on board. The trucks are so fitted and shelved that a large quantity of medicines and surgical material can be carried and so arranged that the contents of every box (which are printed on the outside) are available at a moment's notice. The materials contained in these boxes are those required to replenish the field-panniers, surgical haversacks, and field companions used by the regimental medical staff and bearer-companies. Two of the trucks have at present been sent forward with their *personnel* on board to the principal medical officer and the third truck remains here in reserve, ready to be filled up and instantly despatched by special engine. The idea of this advance train is that it may be pushed as far forward as possible and kept moving from siding to siding as the troops move forward. This plan was carried out in the Colenso battle and there was in consequence no risk of the field force running short of any medical requirement and every medical officer had everything he wanted on an occasion when exceptional demand had to be made.

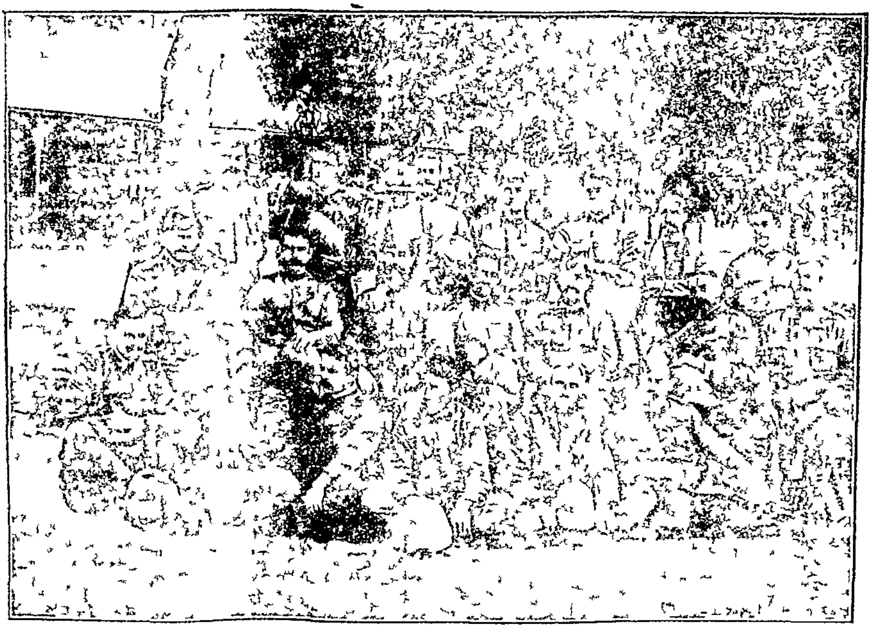
WILLIAM MAC CORMAC.

(FROM OUR WAR CORRESPONDENT.)

Cape Town, Jan. 8th.—Having spent some time in the collection of reliable records I am able to give you the admissions to hospital up to date. At No. 1 General Hospital, Wynberg, they are as follows: 125 officers, 1204 non-commissioned officers and men, 15 wounded Boers—total, 1344. The deaths up to date in this hospital have been three officers and 20 non-commissioned officers—total, 23. At No. 2 General Hospital there have been admitted 580 non-commissioned officers and men. The deaths up to date have been those of 11 non-commissioned officers and men.

The following operations have been performed in No. 1 General Hospital:—Amputations: of the thigh at the middle third, one; of the leg, three; of the thumb, one; of the finger, three; of the arm, one; and of the forearm, one. Excisions: of the elbow, one; of the eyeball, three; of the metacarpal bone one, and of part of the ulna, one Cases of trephining, five, of laparotomy, two, of paracentesis thoracis one, of extraction of bullets, 30, of exploration five, removal of glands one, removal of splinters of the humerus one, and of tumour one—total, 62 In No 2 General Hospital —Amputations of the thigh, one, of the shoulder, one of the leg two, and of the fingers two Cases of trephining, three, of laparotomy, one, of enucleation of eyeball one, of resection of rib one, and minor operations, 15—total 27 The deaths up to date in No 2 hospital were—one from gunshot wound of the skull and brain one from lacerated bladder (gunshot) two from penetrating wound of the abdomen two from scalp wound and fractured skull (gun shot) one from fractured spine (gunshot) one from shock after excision of the right arm excised at the shoulder joint one from tetanus (left thigh and buttock, already referred to) one from dysentery, and one from gunshot wound of the brain thorax and abdomen—total 11

A sad and very curious case was that of a Naval Brigade man A Mauser bullet struck a cartridge he was carrying in his bandolier causing it to explode and enter his abdominal cavity, I regret to add with fatal effect This brave fellow s latest words were that he would not have cared if a Boer had shot him, but to be killed by one s own shot was much too hard lines'



The Staff of No 1 General Hospital, Wynberg

My attention has been called by Colonel Anthonisz Principal Medical Officer 1st General Hospital to the fact that several of the new drugs are not in the scheduled list They are not included either in the Indian list, but out there a rather happy custom prevails to overcome the omission which might with advantage be copied by the authorities at home Every medical officer in charge in India gets an extra allowance of 50 rupees a year to procure any new remedy that he requires No doubt the authorities here would instantly supply what is needed, but a certain routine has to be gone through and much valuable time is often wasted in procuring what ought to be ready at hand to meet a pressing necessity

If every possible care has been taken of Tommy Atkins his wife and children have not been forgotten during his absence at the front A few days ago I had the pleasure of being present at one of Mrs, R Chamberlain's pleasant Christmas treats to the young ones in the schoolroom at the medical camp The tables literally groaned under the weight of good fare for both young and old and the concert which followed conducted by such proficient musicians as Mrs O Brien Lieutenant Chalk and others failed not to interest and amuse all the wounded who were present thereat Mrs R Chamberlain and her willing workers received such a reception as will long be remembered and will doubtless convince them that their labour of sympathy and love was thoroughly and deservedly appreciated by all present

In order to relieve the three general hospitals of convalescent officers a portion of the sanatorium at, or near to Claremont has been secured This building (a fine and imposing structure) was built by an American firm and is located in a healthy and cheerful spot which commands an excellent view of Table Mountain Its accommodation is both ample and good and equals if it does not excel, anything in or around Cape Town It is built in three or four storeys the corridors being both lofty and wide The fittings are modern and the bedrooms (106 in number) are replete with everything necessary for a sick person s comfort There are some 35 convalescent wounded officers located in this charming retreat and all seemed by their own statements to be progressing most favourably towards recovery

Jan 9th —No 3 Hospital Train has just arrived from the Orange River and the De Aar districts bringing down three officers and 50 wounded and sick men, most of whom were located in No 3 Hospital at Rondebosch under the superintendence of Lieutenant Colonel Wood, R A M C and his most efficient staff A few were sent to the Duke of Portland s Hospital at Rondebosch an institution providing 110 beds the whole cost of which has been borne by the Duke It is in charge of Major Kilkelly R A M C and amongst other notabilities on the staff are Lord and

Lady Henry Bentinck, these living at present under canvass.

I am happy to state that in spite of much wind and constant dust storms the health of the troops in the Orange River district remains exceptionally good, and the Red Cross Society, under the very able control of Colonel Young, is doing grand work by a liberal distribution of medical comforts, such as mineral waters, preserves, fruits, and tobacco. These gifts are much appreciated by the troops, who are sensible of the great kindness of the donors. The inhabitants of Cradock district forwarded over £200 worth of goods for the sick and wounded. The woollen pyjama suits served out by the Red Cross Society to all the sick and wounded have been especially appreciated.

Having learnt that some sickness prevails in a military camp distant about 40 miles from Cape Town, I am going there at once to learn all particulars, especially as there is some doubt as to the pureness of their water-supply.

(FROM OUR SPECIAL CORRESPONDENT AT THE BASE.)

Another blank week as far as we are concerned here, as although there has been fighting on the Natal side most of the wounded will be treated in the hospitals and ships at Pietermaritzburg or Durban. We are sending a large draft of sick and wounded home by the *Majestic* which sails on Jan. 15th, about 150 men and 15 officers; this will clear our hospitals pretty well and give us time for a look round and a general brush-up preparatory to receiving any more who may come down from the Modder River and Spytfontein districts when Lord Methuen's division next makes a start towards Kimberley. I was on board the *Majestic* a few days ago and was very much struck by the splendid accommodation which she offers for transport purposes, and I could not help wishing it were possible for the authorities to take up a couple of ships of her size and splendid accommodation for hospital ships. If a ship like the *Majestic* or *Teutonic* were to sail regularly from Cape Town to Netley, say once a month, there would be no necessity for sending patients by smaller boats and the difference in comfort and quickness of passage would amply compensate for the increased expenditure. I maintain that ships of the size and possibilities of the *Majestic* class are much more suitable for the conveyance of sick and wounded than smaller and slower vessels, their great stability alone being a strong point in their favour when one takes into consideration the kind of weather they will meet with in the Bay and English Channel at this time of year. Whilst on this subject I may say that the *Princess of Wales* hospital ship arrived here yesterday, but I hear rumours of sundry mishaps that have occurred on her outward voyage. However, we will hope she will do better on the homeward trip. The *Nubia*, one of the Peninsular and Oriental transports, is being fitted up in a most complete manner as a stationary hospital ship at Durban and should be a very welcome addition to the medical establishment on the Natal side. All our wounded are doing excellently well and I must say I am greatly in favour of treating cases under canvas. The wounds seem to heal in a more rapid way than they do in permanent buildings, not that the results have not been in every way excellent in the hospital wards in No. 1, but I think that the average time has been decidedly less in cases treated solely under canvas as in No. 2. Sir William Mac Cormac returned to Cape Town from Natal yesterday by the *Norman*. He was present at the big fight at Colenso and was able to see for himself the way the wounded were removed from the field, and I understand that he is full of praise for the manner in which things medical were conducted. We expect Lord Roberts and Lord Kitchener to-morrow, but, of course, I know nothing of their intentions, as that is quite out of my sphere, and the lay journals will give you all the news they consider advisable. When the next batch of invalids go we shall have very few in hospital, and they will principally consist of cases that will be ready to go up again in a few weeks or those whom we consider unadvisable to send to England at this time of year. I have absolutely nothing new to tell you. As I stated before, we have had no wounded down for the last ten days, and those who have read my former letters know all about the cases we have in at present, so that till more fighting takes place on our side I shall have no tale to tell.

Wynberg, Jan. 10th.

Correspondence.

"Audi alteram partem."

"THE CONFERENCE AT NEWCASTLE A THE MIDWIFERY QUESTION."

To the Editors of THE LANCET.

SIRS,—I regret that want of time prevented my reply last week to Mr. Haydn Brown's letter of Jan. 20th. I t the clauses of his suggested scheme *seriatim* and will ans them as briefly as possible. 1. I do not think it would practice be possible to divide the responsibility for a c properly or justly, even if at all, between the nurse and medical man, and the attempt would probably lead to mu unpleasant friction in any case that did *not* progress exac as it should; but if, as arranged in Clause 3, the nurse a "virtually as medical practitioner's assistant" the respon bility surely falls on the medical man, and he would have, as in the case of an ordinary assistant, the opportun of dismissing the nurse if he did not think her a good on he could only dismiss her, and that not directly, in the ca of proved and accomplished malpraxis. Clauses 2, 5, a 6 all relate to questions of fee, which I do not think wo or should be embodied in any Bill. The fee in Clause 5 would be quite inadequate for the medical ma since "obstetric nurse's" fee would, I assume, be not than "former midwife's" fee, the medical man's fee be equal to the "cost of common help usually require that is something varying from 1*s*. to 2*s*. 6*d*., in rare cas perhaps as much as 5*s*. What is the intended effect of t medical man's visit as suggested in the latter paragraph Clause 4? The only object I can see is to shift the respon bility—in theory partly, in practice wholly. Clause 7 wou add a new terror to the practitioner's life and would, mo over, create an unworkable monopoly. We are not deali with paupers only who have to take what they can get a be thankful, but with at any rate all sections of the worki class; and the complications likely to arise between medic neighbours and the difficulties of enforcing the rule are fat objections to that clause and to the following one (Clause 8

I am, Sirs, yours faithfully.

Freshford, Jan. 28th, 1900. CHAS. E. S. FLEMMING.

"ANTI-TYPHOID INOCULATIONS."

To the Editors of THE LANCET.

SIRS,—Will you allow me to make a few friendly crit cisms on this subject as recently treated by Profess Wright in his paper in THE LANCET of Jan. 20th, p. and in a leading article in THE LANCET of Jan. 27t p. 245, in view of its asserted importance as a proph lactic measure and as possibly acting as one means rendering the youthful British soldier more immune to adverse conditions by which he is surrounded at home more especially abroad? I take it that the value of an figures adduced as bearing on the relative immunity of th inoculated as contrasted to the uninoculated will depend o the degree to which it can be shown that the cause generally and uniformly in operation in the sections of th community embraced by the figures. When the cause common to many at one and the same time, under like condi tions pertaining to all within its sphere of action, endemic area or localised outbreak, the outcome of results in the inoculate and uninoculated sections is necessarily of high value; when, on the other hand, the incidence of the disease indicate an agency not common to the whole community or a sectio of it but influencing individuals only here and there, an presumably derived from an outside source—sporadic cases the means of accurate deduction are wanting and a element of uncertainty difficult to eradicate is present Now this latter feature is the predominant one in India enteric fever, while endemic and epidemic outbreaks ar rare. The main mass of disease in this country is made u of isolated cases having but little traceable connexion as t source between each other; the enteric cause impresses bu a few of a large susceptible mass, attacking those only who come within its sphere of action, the source being doubtless outside of the barrack limits, little, however, being known definitely of the *conditions which surround this* outside virus or of the mode or media by which it is transferred to the susceptible soldier With such cases the difficulty in tracing exposure to these sources on the part of an inoculated or uninoculated mass of men and of making deductions on the value of inoculation from the instances of disease is great, for although it may be advanced that both sections are equally liable to exposure to the cause yet unless it can be shown that this feature really occurs in individuals of each section in equal proportion a strong element of doubt is introduced into any deduction made which would require large numbers and an extended period to eliminate From the fewness of attacks in proportion to the large susceptible mass always present in our army in India it is apparent that but a small ratio is really exposed to the sources of this sporadic disease in spite of their undoubted existence and how are we to arrive with reasonable certainty to allow of an accurate deduction in this inoculation experiment at the number of each section contained in this ratio? In the instance of the 2nd Gordon Highlanders adduced in the table at p 152 (one of the strongest supports for protection) during a period of nearly eight months following inoculation (the corps being located partly in a hot plain station and partly in several cool hill stations) in 397 inoculated men, the attacks gave a ratio of 0 25 per cent, while in 614 non inoculated there was a percentage of 2 8—an amount in view of the period embraced, not suggestive of marked prevalence of the cause Now, were the predisposing and exciting causes of enteric fever so equally dispersed over the respective sections in these different stations as to allow of acute deduction on the potency of inoculation from the results?

It is apparent from the table that inoculation does not ensure security, nor does it ensure uniformity in results, the ratios ranging from 0 to 2 1 per cent, and these results do not differ much from those known to occur in newly arrived corps irrespective of inoculation

Professor Wright referring to the battery which showed a result opposed to the other corps (one case occurring in the inoculated section and none in the non inoculated) (p 151) mentions as especially noteworthy "the fact that a battery consisting in large part of men newly arrived from home has in the 11 months subsequent to the institution of the inoculation had only one case of enteric fever", but a reference to the known data *of the incidence of disease* in newly arrived corps prior to inoculation will indicate that this is no new feature as complete exemption has occurred in some instances and but a few cases in several I take it that what is wanted is a degree of immunity beyond what has been already recorded

That the tendency of the results as a whole is hopeful and suggestive is apparent, yet in view of the importance of the point at issue and the necessity of building on a wide and firm foundation I would ask whether better fields of observation do not exist In this country the disease is no less prevalent than in India while the circumstances surrounding it are better known The *results so far as reducing* susceptibility or reducing virulence would here be no less valuable than in India while the experience gained would be elsewhere applicable Or if these experiments must be limited to the military section we have in Dublin at home, and in Malta limited circumscribed communities producing an equivalent in disease to India and probably better spheres of action, while in Bermuda relatively in advance of all other stations at home and abroad in the production of cases, we have with greater prevalence of the cause advantages for studying the outcome of inoculation which few other stations possess Certainly the numbers available in this island are not great yet the value of the accruing knowledge would probably be of a high order

I am Sirs yours faithfully,
FRANCIS H WELCH, F R C S Eng,
Lee Jan. 29th 1900 Surgeon Colonel Medical Staff (retired)

"DEATHS UNDER CHLOROFORM"

To the Editors of THE LANCET

SIRS—The article by Dr Edmunds in THE LANCET of Jan 27th p 227, is a strange mixture of fact and theory The opening sentences entirely agree with the opinions of Lieutenant Clayton Lane I M S and myself, the rest of the article consists of praise of Krohne s inhaler and theories of what is supposed to happen during its use *As Dr Edmunds evidently has failed to grasp my contention* may I quote a portion of my letter to THE LANCET of July 1st 1899, p. 53? I then wrote "In THE LANCET of June 17th you refer to a number of deaths occurring during the administration of chloroform, and, as usual I find detailed accounts of the amount of anæsthetic 'used' or 'given' Even where not expressly stated it appears *to* be inferred that if a drachm is 'used the patient gets a fixed percentage of this drachm into his blood *via* the lungs Nothing could be further from the truth Anyone who has given a large number of anæsthetics knows how the depth and frequency of respiration vary in different patients and at different times in the same patient consequently, although it is easy enough to say how much chloroform has been vapourised in a given time it is impossible to say how much of this vapour has been inhaled by the patient The only approximately correct method of calculating this is to administer the chloroform from an airtight inhaler which from the concentrated vapour so produced is rightly condemned as being highly dangerous With many of the elaborate machines now in vogue it is easy enough to blow a certain percentage of chloroform vapour at the patient, the difficulty is to get him to inhale the same at a uniform rate Apart from the saving of chloroform, which is cheap enough, I fail to see any advantage in anæsthetising a patient by means of a cumbrous apparatus and 'using' only half a drachm over the production of the same results by means of half an ounce gradually dropped on a simple mask such as Skinner s If the patient does not absorb a similar dose of chloroform in each case why do we get a similar result?" I am still awaiting a reply to this query In reply to Dr Edmund s query I may say that I set out with the object of inducing anæsthesia slowly and quietly in from about 10 to 12 minutes and of maintaining this state with regular pulse and respiration and contracted pupils I am in the habit of administering chloroform almost daily on lint spread on a metal frame commencing with one minim doses every 20 seconds and gradually increasing the dosage up to five minims or more if required When complete anæsthesia is produced I find from three to five minims every half a minute usually sufficient to keep up regular anæsthesia but I am guided rather by the state of the pulse respiration, and pupils than by any hard and fast rule as to the amount *of chloroform* and vary the amount accordingly In other words I am guided by the state of patient and not by the amount of chloroform which theoretically ought to be used An experience of over eight years hospital in addition to private practice has proved to me the practical efficiency *of this method and its relative* (not absolute) safety as compared with other and more elaborate methods The academical discussion as to whether this is a rule of thumb method or scientific dosage does not interest me The fallacy of comparing a drug administered by the stomach in solid or liquid form with a vapour given from an inhaler *via* the lungs is obvious Theoretically *what we want to know is the amount of vapour which is* being absorbed by the patient not how much we blow at him Practically we have to be guided by its effects on pulse respiration and pupils

I am in agreement with Dr Edmunds in pleading for accuracy in administration of chloroform and if anyone can devise a practical method of estimating the amount of *chloroform* vapour absorbed by the patient, instead of calculating the amount blown at him, I shall certainly adopt it The only advantage of Krohne s inhaler is the saving of chloroform but not of the patient about whom all that the administrator knows is *that* he cannot have absorbed a larger amount than has left the bottle If the patient should unfortunately succumb what consolation is this fact to either the patient s friends or the anæsthetist? It is useless to point at the bottle and say that it cannot be a case of overdose because only one drachm has been used In fact the use of a machine which to a certain extent limits the *diffusion of chloroform* vapour makes it easier to give an overdose with a smaller amount of chloroform As might be expected deaths from chloroform given from Krohne s inhaler are beginning to crop up and will continue to do so How anyone can deceive himself into the belief that any known method of chloroform administration no matter how perfect theoretically, can be absolutely safe passes my comprehension In my own practice in reply to patients queries as to the safety of chloroform anæsthesia I invariably tell them that the risk is us his distrust of ecurity, especially when they med with elaborate machines for what they are term the "scientific" administration of chloroform.

Plymouth.

I am, Sirs, yours faithfully,
C. HAMILTON WHITEFORD.

"SOME FACTS GATHERED FROM EXPERIENCE RESPECTING MISCIBLE BLACK CARBOLIC DISINFECTING FLUID AND CARBOLIC DISINFECTING POWDER."

To the Editors of THE LANCET.

SIRS,—Allow me to offer some few remarks on the above article which is very interesting. Mr. Alexander has done much service to the public and also to the honest manufacturer by calling attention to the matter. Analysis is essential nowadays in nearly everything, especially so when the substances for examination are to combat disease. After very considerable experience in analysis of our own (Messrs. Lawes') fluids and powders, those of other makers, and various preparations of which the phenols are the vital constituent, I consider the determination of the phenols is both hopeful and hopeless—hopeful as regards being able to give a certain opinion as to the value of the preparation and hopeless when extreme accuracy is required. The comparatively simple process which I have carried out thousands of times enables me to control the manufacture, prevent importation of useless material, and have a very solid piece of evidence to show those who will say a good deal to procure an order for their products. I have not had much trouble with naphthalene, but no doubt some makers have; careful inspection by the chemist in charge of the manufacture will get over this. The preliminary precaution of taking a sample by glass rod from the cask, as mentioned in the article, will readily afford a clue on this head. Analysis of the creasote is, of course, very essential.

Now as regards analysis of fluid the method Mr. Alexander gives appears to be very satisfactory, but it seems rather long, and I think for practical purposes might be simplified. My method is almost as given by Tidy (Lunge's "Coal Tar and Ammonia," p. 361, second edition), but I have made some slight modifications which long experience has shown to be easier and without any sacrifice of accuracy. I take 50 cubic centimetres of fluid creasote, &c., instead of 100 cubic centimetres, distil in six-ounce stoppered German glass retort till full of fumes, heat up distillate twice with 20 cubic centimetres of caustic soda (specific gravity 1·200) in small Jena (250 cubic centimetres) flask standing on an iron plate. Shake well; separate by means of a separating funnel or tube. To the mixed caustic solutions add excess H_2SO_4 (one part acid to three parts of water); then measure the tar-acids when cold in a burette. Some of the sulphate of soda solution can be got rid of by the separating funnel. This test can be done in about an hour. The retort is heated direct over an argand, which gives both heat and support. Fracture is not frequent if care is used. There is no danger as there is no explosion—at least, I have not seen one. The lad usually employed in the laboratory can do these analyses very well after a bit. This test, founded on Tidy's, is the sheet-anchor of the business. I believe some chemists do not know about it, or at least its application in this direction, consequently at times ludicrous results are returned which must cause annoyance to medical officers of health who have, I should say, no time to spare. Of course, water, total oils, pyridine bases, alkali, &c., can be estimated if required and do not present much difficulty with a little practice; they are of importance, but for practical purposes of disinfecting the "tar-acids" are the thing. As to powders, distillation in retorts is not, I think, very satisfactory. The retorts crack awfully and I doubt if anything like the true percentage is obtained. Thorpe in his dictionary gives a method, treating the powder with ether and filtering after standing over night. This gets out tar-oils and acids; soda (specific gravity 1·200) is added, which takes up the phenols and leaves oils; part of the ether is distilled off and the rest separated; the caustic soda solution is then treated

sured in a burette esults but is rather long. ittle plan suggested to me by heating a weighed quantity of the powder for a of hours or so at 100° C., and taking the loss indication of phenols is very useful, especially to works chemists, who know what moisture the base of the and acid contain, so that the amount can be the total loss; the remainder, taken as phenols, very closely agrees with the ether method. This plan is specially to tell what is in an unmarked cask, &c., or rapidly check lot going out; it would be of service also to medical men; as if a powder is guaranteed 10 per cent. carbolic and only shows 6 per cent. total loss it is deficient and can then be submitted to further I might venture to suggest that it is desirable to keep disinfectants and carbolic tooth-powders carefully ur control and away from young children; tooth-powder especially apt to get into the eye, causing painful Trusting that these few remarks on the analyses of substances may be useful to medical men whose onero labours are lightened if their patients' surroundings a healthy and clean,

I am, Sirs, yours faithfully,
VINCENT EDWARDS, F.I.C.,
Chemist to Messrs. Lawes, Limited.

Lawes' Works, Barking, Essex.

"THE MURMURS IN MITRAL STENOSIS."

To the Editors of THE LANCET.

SIRS,—Dr. Brockbank's theory, being a modification that propounded by Dr. Barclay and supported by Dr. W. Dickinson and others, it may be as well to recur to the of Dr. Barclay's theory—viz., a case of mitral stenosis which "the contraction of the heart could be felt between the ribs during the pause prior to the occurrence of the sound and while the presystolic murmur was audible to the ear."[1]

Dr. Dickinson supported the theory, stating, "I have satisfied myself and confirmed my conclusion upon many patients that the so-called presystolic murmur does not precede the impulse of the heart, but begins with it."[2] whole subject was thoroughly discussed in your columns in the years 1872, 1887, and 1889; there is therefore no occasion for reproducing arguments that have been used against this theory and which are equally applicable to Dr. Brockbank's modification. One question, however, of Dr. Dickinson's is, I think, important: "Does the lifting of the chest-wall felt by the finger indicate the systole?"[3] My answer to this is, that the systole of the *right* ventricle is felt, but it does not necessarily follow that the left ventricle is also in systole.

In an article entitled "A New Explanation of the Presystolic Bruit," in the *Clinical Journal* of July 12th, 1899, I recorded a similar case to Dr. Barclay's. Until I met this case I did not appreciate the significance of the "lifting" movement, concerning which so much has been written. palpation the right ventricle could be distinctly felt contracting during almost the entire diastolic period of the le ventricle, the contractions spreading from base to apex an ending with the apex beat. The theory I have ventured t bring forward is as follows: 1. That in consequence of the different tensions existing in the right and left ventricles these cavities, under the circumstances of mitral constriction, do not act synchronously. 2. That the base to apex portion of the right ventricular systolic wave occurs when the left ventricle is in diastole. 3. That the right ventricular muscle vibrations are heard during the diastolic period and that they gradually increase in intensity towards the end or it. 4. That the so-called presystolic bruit is composed of three parts—(*a*) right ventricular muscle vibrations, (*b*) an auricular systolic bruit, and (*c*) a slapping first sound; the muscle vibrations being the cause of the peculiar and intimate relation between the auricular systolic bruit and that sound. 5. That in double mitral murmur these vibrations prevent the distinction between the two murmurs which is heard in the double aortic murmur.

The supporters of the "Barclay theory" have, I think, erroneously assumed that the right and left synchronously We know that in many cases of mitral stenosis the left auricle is incapable of contraction, and that the circulation is carried on by the hypertrophied right ventricle and pulmonary arteries The question may therefore be asked, Could the circulation be carried on in a case of mitral stenosis if the two ventricles acted in perfect synchronism? I do not think it could

THE PREVENTION OF SYPHILIS BY TREATMENT

To the Editors of The Lancet

Sirs —Syphilis being a contagious disease ought if possible to be prevented either by notification and prosecution of persons who voluntarily infect their neighbours or by some other legal plan *Professor Alfred Fournier* has favoured me by sending me his recent pamphlet on the prevention of syphilis by treatment, from which it appears that he considers the Parisian plan which has had so many imitators in Europe of no service for prevention and recommends simply our present British system of hospital treatment of the poor affected with the disease Here are one or two citations from his pamphlet "Applied from early times to the repression of prostitution administrators and police measures have without doubt accomplished in relation to the prevention of syphilis all that they are capable of accomplishing *But without refusing to recognise the benefits* (as to which I would be on my guard as against ingratitude and error) one is yet free to regard them as insufficient for their purpose it being understood that their action is necessarily limited to public control The police only supervise some thousands of women whilst there are eight or ten times that number who spread abroad syphilis professionally among the Parisian population The police conscientiously do all the good they can and we should be thankful to them, but they are powerless to stop the overflowing current of venereal maladies In spite of the system syphilis still exists among us as it did in the past as an incurable ulcer attacking society I believe that it has increased, although sufficient and reliable statistics are not obtainable This is also the belief of my colleagues whom I have frequently heard saying, 'Syphilis is to be seen every day, everywhere, and worse than ever' At any rate I am in a position to affirm without fear of contradiction that at the present day syphilis flourishes It abounds in hospital wards, in the hospital and out patient departments, and in our private consulting rooms, &c &c

At the Portsmouth meeting of the British Medical Association some speakers in the debate on the Prevention of Venereal Contagions seemed to wish to introduce the Parisian system into London The above cited remarks from Professor Fournier show that this plan is always a failure because so disgracefully unjust in its application Perhaps notification might succeed if it were anonymous, as it would give us correct information as to the extent of the evil and allow us to formulate plans for its prevention

I am, Sirs, yours faithfully,
Charles R Drysdale,
Consulting Physician to the Metropolitan Hospital

London Jan 29th 1900.

GRIFFIN v PEIRSON AN APOLOGY.

To the Editors of The Lancet

Sirs —As the solicitors for the Medical Defence Union, Limited acting upon their instructions for Mr Griffin of Banbury in the libel action of 'Griffin v Peirson,' which was entered for trial at the present Oxford Winter Assizes, we beg to hand you a retractation and apology signed by the defendant and witnessed by his solicitor for publication in the press May we, therefore, ask you to be good enough to insert it with this letter in the next issue of your journal

We are, Sirs yours obediently,
Hempsons

[illegible] King street, Cheapside, London EC Jan 30th, 1900

Apology

Whereas I the undersigned Alfred Mellett Peirson otherwise known as "Lennox" of No 30 Blenheim mansions Edgware-road London spoke published and caused to be circulated in the months of May and July 1899, certain slanderous and libellous statements concerning Dr Innes Griffin of Banbury, Oxfordshire, in relation to an operation which he had performed upon a patient for a mastoid abscess in the month of October 1898 and by which I imputed to Dr Griffin a want of professional care and skill in connexion with the operation And whereas Dr Griffin has taken action against me for libel in the Queen's Bench Division of the High Court in consequence of the statements published and circulated by me as aforesaid but has kindly consented to forego such action on my withdrawing each and all of the said statements and making the apology herein contained and paying a certain agreed sum for costs: Now I, the said Alfred Mellett Peirson otherwise known as "Lennox" hereby declare that the said statements so published and circulated by me as aforesaid are each and all of them without any foundation whatsoever in fact and I hereby apologise fully, freely and unreservedly to Dr Griffin for having published and circulated them and desire to express my sincere regret and contrition to him for any pain and inconvenience which I may have caused him for having so acted as aforesaid and I am grateful for the leniency shown to me by Dr Griffin And I hereby authorise Dr Griffin to publish this apology in such manner as he may think fit

Dated this 29th day of January 1900
Witness—Jno D Clay Solr.,
185A Marylebone-road, W
A M. Peirson

"PROPOSED PUBLIC MEDICAL SERVICE"

To the Editors of The Lancet.

Sirs —Referring to Dr Rentoul's letter *re* the above scheme I have not had the good fortune to see his rules and suggestions but hope to do so in the near future As regards a "cash fee department," by this I understand an abolition of the contract system in favour of "cash fees" at a reduction from the practitioner's ordinary charges This scheme I venture to consider as quite inadequate—if not totally impracticable—as a means of competing with the medical aid and similar institutions I had the good fortune to be present at two or three debates upon this very subject, when after considerable discussion the idea was dropped as impracticable for the purpose intended—namely, to compete with associations that at present undertake contract work The public are wedded to the provident or contract system and will not readily abandon it I am pleased to see that Dr Rentoul so far agrees in that he has recommended a provident department also

The proposed service would exactly fill Dr Rentoul's second suggestion—namely, "to enable practitioners to refuse to have anything to do with club or contract work save through the service,' and with that object in view the rules have been so framed that every practitioner is eligible to join whether holding a medical aid appointment or not, but in the case of certain appointments that may after due consideration be condemned by the executive of the service then a long but definite period will be given to the practitioner to enable him to decide whether he will continue a member of the service and work up a connexion therein or will continue to hold the condemned appointments and resign his membership or be expelled failing resignation To prevent wholesale condemnation of appointments without most careful consideration it is provided that the executive shall not condemn any appointments until after the expiration of a fixed period from the inauguration of the service or until they have consulted the district committees as to the advisability of so doing

Dr Rentoul's fear "that such a service would run a great danger of being ruined by not having a rigid 'wage limit' for membership and thus hospital abuse if corrected at the hospital would not be cured but only transferred to the service doctors are a most unbusinesslike class," is worth careful consideration The first portion I would meet by saying that it is provided that the management and control are solely in the hands of registered medical practitioners duly elected from and by the general body of members of the service If they found that a certain wage limit did not pay they could raise the premium or lower the wage limit, at any rate for all new patients The latter remark is more difficult to combat, but an endeavour has been made to do so by framing the rules on business lines and embodying in them certain rules and directions as to working, failure to comply with which may be visited by a fine, moreover, no one man is entirely trusted to work the details either of the district committees or executive council but a system of checks has been adopted by which the [illegible] each other off and are again checked off by the district committee who in their turn are [illegible] the exec[illegible]

As regards changing the name [illegible] Publ[illegible] Service to the "Provident Medical Service" I can [illegible] grave objection to this course if [illegible] is to be started, though [illegible] public" serves more clearly to distinguish the service from already existing "provident" associations which are only provident in name—as, for example, the Coventry Provident Dispensary, to combat which the Coventry Public Medical Service was successfully established. Having resided many years in Coventry, I am able to state that, at least until lately, the service was working well, with satisfaction to the staff and to the patients, and to the best of my knowledge it is still flourishing. What we now require is an amalgamation of the various public medical services into one large association.

I am, Sirs, yours faithfully,
York-road, Ilford, Jan. 29th, 1900. MURTAUGH HOUGHTON.

"THE UNIVERSITY OF LONDON ELECTION: THE CANDIDATURE OF DR. W. J. COLLINS."

To the Editors of THE LANCET.

SIRS,—Dr. Savill is quite correct in supposing that my letter of Jan. 13th was intended to indicate decided opposition to the candidature of Dr. Collins, though whether it can be called "virulent" or not must be a matter of opinion. He charges me with "at least *one*" *misstatement* of fact, but he does not say what even that one is. Dr. Savill misses the point at issue, which is not whether Dr. Collins is a man of "vast knowledge" or whether he took a distinguished position at his university examinations. The latter statement may be fully admitted and the former may also be conceded, for the sake of argument, without either of them weakening the position taken up in my letter. Indeed, they strengthen it. For the vaster Dr. Collins's knowledge and the higher his academic distinctions the more they would seem to reflect on the intelligence of the great majority of the medical graduates whom he aspires to represent and who differ with him so largely on one of the most vital questions on which the medical profession is brought into relations with the general public. I would appeal to the "hundreds" of Dr. Collins's fellow graduates, and especially to the "large number of medical and surgical alumni" of the University of London who are claimed as supporting his candidature, to consider carefully what his success will mean. It will mean that the pertinacious emissaries of the National Anti-Vaccination League, who now put Dr. Collins forward as one of their most authoritative scientific patrons, and who quote the fact of his having been Chairman of the London County Council as evidence of his distinguished public position, will then be justified in representing him as the acknowledged mouthpiece of the medical graduates of the University of London. How any London graduate who not only believes in vaccination, but who believes also in the importance of pressing its adoption on the public, can lend himself to such a candidature is one of those curious problems in psychology and morals which are an inexhaustible puzzle. Dr. Collins would be as inappropriate a representative of the medical graduates of the University of London in Parliament as he would be a fitting one for Leicester.

I am, Sirs, yours faithfully,
M.D. LOND.

LITERARY INTELLIGENCE.—We are glad to know that the New Sydenham Society proposes to reprint in a forthcoming volume of selected papers an essay first published in 1840 by Mr. George Bodington, who organised at Sutton Coldfield, in Warwickshire, an institution for the treatment of consumption on the liberal diet and open-air plan. He anticipated most completely all that has recently been written abroad and at home on this topic. He published a booklet of some 60 pages describing his plans and his success. The essay was referred to in THE LANCET of Nov 26th, 1898, p 1433, in a letter from Dr. A. Tucker Wise, but the matter was brought to the notice of the council of the Sydenham Society through Dr. T. Barlow, by Dr. S. T. Pruen of Cheltenham. Apart from its intrinsic interest it is a matter of justice to an English surgeon of the past generation that it should at the present juncture be re-published. We understand that it will be accompanied by the original paper of Dr. Hodgkin describing the disease which now goes under his name and by a selection from the eminently practical memoirs on obstetric subjects of the late Dr. Braxton Hicks.

THE ORGANISATION OF THE PROFESSION.

THE CORK MEDICAL PROFESSION ASSOCIATION: THE HISTORY OF THE ORGANISATION AND OF THE FIVE YEARS' STRIKE.

(FROM OUR SPECIAL COMMISSIONER.)

CORK holds an honourable position in the vanguard among those towns where the first efforts were made to organise medical unions. It was here that one of the first, if not the first, medical strike occurred, and to a certain extent it may be said that this strike is still continuing. Indeed, this seems to be the way with medical strikes. There is a period of sharp, acute struggle, certain positions are taken, others are lost, then both parties remain facing each other for years. The violent struggle is over, but peace is not made and both sides wait passively for the slow process of disintegration which in the course of time will gradually disperse what power of resistance remained. From time to time echoes of the struggle at Cork have reached our shores, and paragraphs concerning various episodes in the contention have appeared in the papers, but there has been no systematic attempt to give a complete history of the movement. So far as limited space will allow I shall attempt to supply this deficiency. This account will show what organisation can do and will constitute an encouraging example for the members of the profession practising in other towns.

Some 60 years ago the City and County of Cork Medical and Surgical Society was founded. Practically it was simply a medical social club. The members met and dined and read purely scientific papers. But on May 13th, 1892, they held a meeting to consider the advisability of re-establishing the Cork branch of the British Medical Association, either to replace or to act in conjunction with the Medical Society. For this purpose 11 practitioners signed a circular convoking all the members of the British Medical Association established in the locality to meet on June 4th. The object of this meeting was not merely to resuscitate the Cork branch of the Association but to draw up a plan of action dealing with ethical questions that concern the medical profession. The meeting was held and the following resolution was carried unanimously:—

> That the branch be re established and be peculiarly devoted to the discussion of ethical questions, and in no way to interfere with the work of the Medical Society.

The meeting also elected a committee to draw up rules, and a general meeting to approve the same was convoked for June 18th. By that time 40 practitioners had already joined; and even at this early date the question of canvassing by the agents of benefit societies and medical aid associations was raised. So quickly did the interest in this question spread that the temporary council of the newly re-constituted branch of the British Medical Association found itself impelled to convoke a meeting of the South of Ireland Branch Council to consider the whole question of club practice or contract work. This meeting was held on July 13th, 1892; and on that occasion Dr. Ashley Cummins complained that the medical officers of the clubs were sometimes called upon to attend the country relatives of members though the latter had only come to town for a short visit. A few days later another meeting was held, and then it was agreed to draw up a circular containing 12 questions to be sent to all the members of the profession in Cork and its neighbourhood with a request that they would answer the questions. On Oct. 12th following a meeting was held to consider the replies that had been received, and these replies supplied the basis of the rules that were ultimately drawn up. Thus it will be seen that great care was taken to ascertain what were the needs and opinions of the profession before attempting to impose rules and obligations. This is very important, for a constitution that is workable, that is freely accepted even though it may have some defects, is better than a model constitution which is not fully appreciated or approved.

With some slight modifications and additions, the rules then adopted have been maintained to the present day. The most important are those which deal with contract work.

First it is stated that the scale of remuneration for such club practice shall be fixed in proportion to the income of the subscribers or members, and that, when the income cannot be ascertained, it shall be estimated according to the valuation of the dwelling-house. If the member's income is under £100 or the valuation of his dwelling not more than £7 10s., the annual subscription shall be 7s. 6d. Above these figures but under £200 income or a £15 valuation of the dwelling the subscription must be 15s., and no one whose income is above £200 shall be admitted. The maximum distance for attendance is two miles from the General Post Office. Then we find the fundamental rule and principle of all unions that "no medical man shall take an appointment from which another retires in consequence of his society or club not complying with these rules." But another rule states that when a medical officer retires from a society because he has not been fairly treated he must first submit his case to the committee and must not send in his resignation till such action has been approved by the committee, and then he will be supported by all the members of the profession. In regard to the detail of the work there is a rule to the effect that if a member subscribes to two societies he shall only call upon the services of the medical officer of one of these societies. If the medical officer of the other society is also called in then he must be paid the fee of a consultant. An extra charge is made for anæsthetics, midwifery, and premature confinements, and this shall not be less than a guinea. The above charges include attendance on the family, but a rule stipulates that this shall mean only relatives who are entirely dependent on the member. Another rule demands the absolute abolition of all personal canvassing for clubs and benefit societies. The secretaries of the different societies are called upon to supply the committee with a list of their members which will be held as private and only accessible to inspection by the committee assembled. These rules apply to all contract work except when the contract is for £5 per annum and upwards for each member and his family.

Such are the main points which were agreed upon during the year 1892; but of course here, as elsewhere, the difficulty arose as to how these rules were to be enforced. Practically the only weapon is the "boycott," and this is established by Rule 16:

> That any member of the medical profession who wilfully violates these rules be excluded from professional intercourse.

Hardly had these principles been discussed and accepted than an occasion occurred to enforce their application. In March, 1893, Dr. Collins informed the committee that he proposed to resign his position as the medical officer of the Bakers' Society. This society paid him a fixed salary of £30 a year, and as there were 120 members this made only 5s. instead of 7s. 6d. per member; therefore the proposed resignation was approved. A few weeks later (on May 27th) the branch as newly re-constituted was officially recognised by the Council of the British Medical Association. In a short time many other questions began to claim the attention of the members. Prominent among these was the question of hospital abuse, and at the same time many further attempts were made to persuade all the practitioners of Cork and the neighbourhood to join the organisation. Early in 1894 a resolution was passed and forwarded to all the Members of Parliament elected in Munster in favour of a Bill for the superannuation of Poor-law medical officers. After several discussions on these two questions it was resolved:

> That two representatives from each hospital staff be elected to meet a chosen deputation of the Poor-law medical officers.

This meeting took place in May and four hospitals and the Poor-law Medical Officers' Association were represented. They adopted a resolution affirming the existence of many abuses and calling on the management of the hospitals to help to abolish the same and to form for that purpose a joint sub-committee. At about the same time the medical officer of the Central Hall Methodist Benefit Society was called upon to give an account of himself and he replied that he had not infringed any of the rules. The question of the wage-limit was again very fully discussed and the limit already established was not only confirmed but on Oct. 25th, 1894, it was decided to send a circular explaining these conditions to all the clubs, benefit societies, &c. It was also agreed that though 7s. 6d. was to be the minimum charge for a member and his family this should not include drugs. The medical officers were as a general rule to prescribe but not to provide drugs. The dispensing chemists, who throughout have sided with the medical men in the struggle, though unsolicited, came forward voluntarily and offered to contract with all members of clubs who accepted the conditions of the medical profession and to supply them and their families with the necessary drugs for 5s. a year. All the dispensing chemists of the town have now agreed to these conditions, so that the members of the clubs can select any chemist according to their convenience and preference.

The position, it will be seen, differs considerably from what generally prevails in England. Though the wage-limit of £100 a year is high, the subscription of 7s. 6d., plus 5s. for drugs, would also be considered high in England if it applied to a single individual. But at Cork single men hardly ever join benefit societies or clubs and the subscription entitles all the family to medical aid and medicine if they are dependent on the members for their sustenance. It must also be borne in mind that marriages are more frequent in Ireland than in England and there is not so large a proportion of single men. But still the question will be asked, What becomes of these single men? for they exist though they may not be numerous. Are they forced to pay the traditional guinea fee? I was assured that the guinea fee was a pure fiction. The workman pays what he likes or what he can afford, and it does sometimes happen that they do pay the full guinea; but then it covers a long bout of illness and not, as sometimes imagined, a single consultation.

In answer to the circular addressed to all the clubs, only two Jews' societies and four other clubs replied accepting the terms laid down by the medical men, and these were but small organisations. 20 clubs or societies refused to entertain the rules. These 20 recalcitrant societies employed nine medical officers, and at the end of December, 1894, their nine medical officers without hesitation simultaneously forwarded, in registered letters, their resignations. To prevent any undue suffering among the members they offered to continue attendance for one month, but would cease further attendance if by that time their conditions were not accepted. In the interval the clubs held a big meeting at which it was decided that the rules as proposed by the medical men should not be accepted and that they would advertise and import medical men from other districts to do the work. Thus, at the beginning of the month of February, 1895, the strike of the Cork club medical officers commenced. The clubs succeeded in importing four outside medical men to do the work of their nine medical officers who were on strike. The new-comers were approached by the medical men of the town and their true position was explained, but they were already well acquainted with the situation and showed that they had no feeling of solidarity with the other members of the profession to which they belonged. The acuteness of the struggle which was now beginning forced the Cork and South of Ireland Branch of the British Medical Association to alter its constitution. Several practitioners who were involved were not members of the British Medical Association and yet it was indispensable that they should be members of the local medical organisation, which, indeed, must be a union of the entire profession. Therefore the title was changed to that of the Medical Profession Association, including in its ranks the local branch of the British Medical Association and all other medical men practising in the district. The members of the profession being thus firmly welded together a strong feeling was manifested that those who fought for the interests of all should not be allowed to suffer. It was therefore resolved to start a strike fund, and it was willingly agreed that the senior practitioners should give £20 during the first year. The others might give less, but the minimum was £5. In this manner nearly £400 were realised and the greater part of this sum was subscribed in a single afternoon. This in itself suffices to show how strong was the feeling and how enthusiastic was the support given to the movement. Outside help was also obtained, notably from THE LANCET and the *British Medical Journal*, the subscriptions received through these papers amounting to about £125.

In one respect, however, the movement was badly managed, and the same blunder has been committed by medical men in other towns. They failed to conciliate the working classes. As the action they were about to take affected principally the working classes it is obvious that their first care should have been to educate the working men to a true understanding of the purpose which they had in view. This should have been a movement of the working class and the medical men against interlopers belonging to other classes. For instance, a large tradesman of the town belonged to one of the benefit societies, and so did a manufacturer and a professional man. What right had these men to be in an organisation created exclusively for the wage-earning class? Several club members possessed incomes up to and even exceeding £1000 a year. Some of them were justices of the peace, others managers of large businesses. It will hardly be credited, but it is the fact, that a few of these wealthy people not only availed themselves of the assistance of the club medical officer, but actually asked for certificates of illness so that they might claim the 7*s*. 6*d*. weekly sick allowance intended to help poor men in the hour of need. The presence of these wealthy members in the ranks of the benefit societies entirely altered the character of such institutions. Instead of being organisations that might justly claim general sympathy and approbation as teaching poor men to be provident, they had been allowed to provide rich men with the means of making niggardly economies. They robbed the medical man of the time he should have devoted to the care of the poor. Therefore it was to the interest of such clubs not to accept wealthy members. But all these points were not driven home and even the trades-union papers abused the profession. As for the wealthy members of the clubs, who were the cause of all the trouble, they complained lustily against their medical officers on strike, but when they fell ill they sent for these medical men and preferred to pay them proper fees to employing the intruding medical men in the service of their clubs. Indeed, these interlopers were in no wise popular and one of them was publicly snowballed by some medical students. This led to proceedings at the police-court, and on Feb. 19th, 1895, one of the students was fined 10*s*. and the others were discharged. In spite, however, of police prosecution and the active support of the clubs the four imported medical officers have not prospered. The medical man who was snowballed died the following July and the clubs were not able to import anyone else to take his place. No professional intercourse was held with these four club medical officers. If one of their patients wanted a consultant the patient was first compelled to dismiss his club medical attendant. Several such cases occurred. Nor did the intruding medical men succeed in making friends in the town.

In August, 1895, the mayor of Cork made an attempt to settle the dispute, and persuaded delegates from each side to meet. This conference was amicable and at one moment it seemed as if peace would be concluded. The delegates of the clubs seemed to recognise that the rules drawn up by the medical men were reasonable and they presented to the medical men for signature a document which the latter imagined to be a copy of these rules. Acting in confidence the medical men signed it, and only afterwards discovered that it was not a copy of their own rules, but that those rules had been very much altered. This caused a great disturbance, as, of course, the signatures given under such a misapprehension were held to be valueless. The clubs also insisted that the remaining three medical practitioners whom they had imported into the town should be maintained in their position and recognised by the profession. This stipulation was absolutely inadmissible; consequently the dispute continued and became more and more venomous.

While the strike was progressing several speculating companies sent agents to Cork and tried to profit by the dispute to establish branches of their insurance businesses. The first in the field was the National Medical Aid Society, Limited, but all the local practitioners refused to have anything to do with this venture. Then the Canadian Order of Foresters wanted to establish a branch at Cork and they were followed by the Rechabites, but no allurements could persuade any of the Cork practitioners to accept the offers which they made. The endeavours of these societies or companies awakened the profession to the realisation of a danger for which they had not yet made any provision. Consequently a resolution was passed on Jan. 1st, 1896, to the effect that no new medical aid society or club should be formed in Cork unless it had obtained the approval and consent of a general meeting of the medical profession. This led to a renewal of proposals that had formerly been made in favour of establishing some sort of coöperative provident organisation to be managed by the medical practitioners themselves. A committee was now appointed to study the question and propose rules, ways, and means.

In January, 1896, the first balance-sheet of the strike fund was issued. This showed that £219 4*s*. 8*d*. had been paid out as strike allowance and that £306 16*s*. 9*d*. still remained in hand to continue the struggle. The payments were made in proportion to the former known receipts. The strike allowance given was equal to two thirds of the annual receipts, except in those few cases where the club medical officer provided medicine, then a further reduction of 3*s*. per annum per member was made. It was found that two thirds of the annual sum received from the clubs against which the strike had taken place was ample compensation, because some of the patients followed the practitioners, and out of the old clubs there was the means of forming the nucleus of a private practice. Indeed, this seemed so promising that it soon became probable that the strike allowance need not be continued for more than one year, and this proved to be correct. The medical men who were on strike had in a year's time built up new positions, and when, after some 12 months, the strike allowance by general consent ceased there still remained £80 in hand. Nevertheless there are considerable impediments in the way of reform. For instance, if a member of one of the clubs against which the strike still continues does not call in the club's medical officer he cannot get a medical certificate that will be recognised by the club and on which sick allowance will be paid. Therefore, if a member of a club calls in one of the practitioners who are on strike he has not only to pay this medical man the usual fees but he loses his right to claim sick allowance. Yet one of the medical officers on strike had, on the day I met him at Cork, been called in by one of the club members and was paid £1 for his services, and the patient had further the courtesy to apologise for having caused him to come out during exceptionally bad weather. Indeed, the medical officers on strike now make larger incomes and work less than they did before the strike. One of the medical officers of the clubs explained to me that before the strike he made a list of all his visits to the houses of the members of his club, and he found that his receipts were equal to 4*d*. per visit, and this did not include the numerous consultations which he gave at home to the club patients who were well enough to come to his surgery. Thus by allowing 4*d*. for each visit the consultations at his surgery were given gratuitously. He then received 6*s*. a year from the Foresters' Benefit Society and had to attend whenever called upon to do so. Now he is at liberty to refuse. But after the strike he was sent for by one of the Foresters and received during the course of the year £20 from this one patient, whereas on the old terms it would have taken 66 years to earn the same amount. Other members of the Foresters' Society, rather than lose their medical man, pay him a retaining fee of £5 a year while formerly they only paid 6*s*. From another patient he had received £46 in four years instead of 24*s*. Another medical officer told me that he had two patients at £5 a year each instead of 10*s*. The fact that such high payments are freely made shows that these patients are well enough off not to have any need to join a working men's provident organisation.

During the years 1896 and 1897 nothing more of any great importance occurred except that the better class of trained nurses and midwives joined the medical men's strike. They refused to attend any of the club patients who had not accepted the terms which the Medical Profession Association sought to impose. During the following year very ardent discussions were held as to the possibility of the medical practitioners themselves establishing a provident or benefit society under their own management. This was finally accomplished and the society was floated and registered in January, 1898, under the title of the Cork Medical Benefit Association. During this year there was a great disturbance within the ranks of the Church of Ireland Young Men's Association. This organisation had a medical aid branch under one of the three imported medical men remaining in the town. But now their medical officer determined to leave Cork, and, strange to say, before going he advised all his patients to accept the terms of the Medical Profession Association. The majority of the members of the Church of Ireland Young Men's Association were disposed to follow this advice, but the minority wanted to follow the opposite course. The question was put to the vote and the majority carried its point. Then the minority made so great a disturbance that the committee of the Church of Ireland Young Men's Association proposed to dissolve their connexion with them; but before this could be done a new managing committee had to be elected. The election was fought out exclusively on the question of the minority and all the candidates were defeated. The latter appealed to the entire association; therefore a general meeting was held and here again they were beaten. After this a split took place; the minority formed itself into a separate organisation with a medical man in attendance. The majority kept possession of the premises of the association and are now working in complete harmony with the Medical Profession Association. They have prospered so rapidly that there is a larger number of members than there was before the split.

Other successes have been achieved. Thus the North Parish Sick Poor Society abandoned the struggle and reappointed their old medical officer under the rules established by the profession. During the year two more societies seceded—namely, two branches of the Irish National Foresters, with 190 members and 90 members respectively, and took back their former officer according to rule. Also, one of the two remaining intruding medical officers recently left Cork and has been replaced by a medical man who had only just become qualified and had not yet been in practice. Only 12 societies are still standing out and these two medical officers have to attend to all their members. It is true that, with the exception of the St. Finnbarris Society, which has increased its membership to 280 members, the 12 societies are not prospering. The membership of the Ancient Order of Foresters has fallen from 234 to 100. The St. Nicholas Society and the Queen-street Society have also suffered from a great decrease of membership. The Central Hall Society out of 80 members had 20 enjoying incomes of from £200 to £500 a year. This society is now in a bad financial condition, its membership is reduced by about half, and they belong to a much poorer class. Thus the hostile forces are gradually dwindling; the imported medical officers have been reduced from four to two On the other hand, the Cork Medical Benefit Association is making good progress. The members have the choice of 12 medical officers and of all the consultants. Nor are any of these medical officers likely to be overworked and therefore compelled to neglect their patients, for there is a rule that they must not have more than 400 subscribers on their books. There is also a rule that no fully recognised hospital surgeon or physician shall take club practice, thus giving the younger practitioners a better chance of making their way; but all practitioners may make individual contracts if for not less than £5 without medicine. Though in the Directory the names of 71 medical men will be found as residing at Cork, many of them are not in practice, have died since the publication of that list, or are now away in South Africa. In actual practice there are not more than 56 medical men, including the two imported. The secretary, Mr. Philip G. Lee, informs me that when a meeting of the Medical Profession Association is convoked he sends out 49 notices. Thus it will be seen that the members of the profession at Cork are almost unanimous and are nearly all in union. It may therefore be fairly anticipated that complete victory is only a question of time. This is the more certain as not one single member of the union has deserted the cause. Such devotion and steadfastness are all the more admirable as there were many and great temptations held out to the junior and less prosperous members of the profession. Yet it has been a hard fight and the means employed to attack the medical profession were not always fair and above-board. Thus a local paper published antagonistic letters apparently signed by fictitious names. In any case registered letters were sent to the supposed authors of these communications, and as the letters were returned by the post-office it would appear as if the correspondents did not exist All these and many other manœuvres have, however, proved futile. The strike has lasted five years. Several of the clubs have given way and the medical officers who resigned their positions are now making better incomes with less trouble than they did formerly, so it is quite certain that they will not give way. Under these circumstances the Cork medical practitioners are quite satisfied to hold out another five years if necessary. They have only to remain true to each other and their position must improve from day to day.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Dose of the Plague Prophylactic.—Official Instructions about Inoculation.—The Progress of the Epidemic.—The Need for a Pasteur Institute.—Plague Measures in Bengal.

EXPERIENCE has shown that the doses laid down in the instructions for the use of the plague prophylactic by M. Haffkine require revision. It has been found that children are less affected by inoculation than adults and can be given proportionately larger doses. Accordingly new rules have been promulgated and official instructions for the use of the plague prophylactic have been sent out. Considerable improvement has been effected in the matter of packing and fitting up the bottles. At one time this appears to have been carried out very insecurely and many bottles of the fluid were found to have undergone decomposition. The following dosage is now ordered:—

	If the dose marked on the bottle is	
	2·5 c.c. then give—	5·0 c.c. then give—
Below 2 years	0·5 c.c.	1·0 c.c.
From 2 to 5 years ...	1·0 c.c.	2·0 c.c.
„ 6 to 11 „ ...	1·5 c.c.	3·0 c.c.
„ 12 to 15 „ ...	2·0 c.c.	4·0 c.c.
„ 16 to 50 „	2·5 c.c.	5·0 c.c.

It is thought that persons over 50 years of age should get 0·25 cubic centimetre less for each decade above that age.

The official instructions contain the following paragraph indicating the usual symptoms of plague inoculation: "The symptoms commence, as a rule, three to five hours after inoculation and consist chiefly of swelling and pain at the seat of inoculation and of a rise of temperature. The pain is felt particularly on movement of the part. The fever is accompanied by general discomfort usual to this condition. No treatment of the symptoms is required beyond applying ice for the relief of headache, if any is felt, and enjoining some rest. General symptoms subside after 24 to 36 hours; the pain at the seat of inoculation lasts for three or four days, disappearing gradually; a painless induration remains for some time longer. It is desirable to produce a rise of temperature to at least 102° F. If the reaction is less marked the operation may be repeated three or four days later with the same or an increased dose, according to the result of the first inoculation. There is no harm in leaving a longer interval between the two inoculations. No changes in diet or occupation are necessary, beyond if possible ensuring some rest. Bathing in the open air should be avoided for some days. A simple purgative may be given 24 hours after the inoculation."

Beyond the very serious increase of mortality in Bombay city there is little to record as to the course of plague in Western India. In Bengal, however, the long-dreaded development of the epidemic seems to have begun in earnest. Reports from Barisal, in the delta of the Ganges, show that the disease has been very rife and I now hear that it has broken out in Patna city. Official returns keep these facts silent. In Calcutta the disease seems to be subsiding after the long-continued low mortality since the outburst last March. The same thing occurred at the corresponding period of the first outbreak, so that a period of quiescence may be expected at least for some weeks. After that interval a renewed development may be expected.

In Bombay city the weekly general mortality has increased from 1642 last week to nearly 1900. These figures mean that there were at least 1200 deaths above the normal. The official returns of plague give less than 400 deaths as due to this disease—a discrepancy which shows palpably the incorrectness of these returns. To cover increased deaths from ordinary diseases it may be therefore safely estimated that there have been *1000 deaths from plague in Bombay city during the past week* I hear that inoculation is finding more favour in Bombay, but the increased number of applicants seems largely due to private enterprise and to measures of "compensation."

Five weeks ago the general mortality of Bombay city was returned at 1049. Poona and Karachi are now practically free.

The necessity for the establishment of a Pasteur Institute in India can be readily seen from the increasing number of patients sent to Paris from India year by year. From the year 1886 to 1896, that is, during the first 11 years of this treatment, out of 3396 foreigners treated in Paris only 95, or less than one-thirtieth, went from India, while 870 went from England. In 1897, however, out of a total of 175 foreigners no fewer than 33, or over one-sixth, went from India and only 83 from England. In 1898 out of 132 foreigners no fewer than 56, or nearly one-half, went from India and only 25 from England.

An attempt at something like active plague measures by the Bengal Government is notified in the *Calcutta Gazette.* "In any case in which the sub-divisional magistrate or health officer thinks fit he is authorised to isolate the house, village, or part of a village in which a case of plague is believed to have occurred by cordons, patrols, or in such other manner as he may think expedient. When action has been taken by the sub-divisional magistrate or health officer under this rule no inmate of such house, village, or part of a village shall leave the same or shall hold any communication with any other person, and no other person shall enter the same or hold any communication with the inmates except in accordance with such directions as may be given by the sub-divisional officer or health officer." Here it is seen almost for the first time that the health officer is given powers in addition to the civilian officer. The actual carrying out of the measure must, however, devolve on the magisterial authority. If the two officers failed to act in harmony the regulation would of course fall through. The same thing would probably happen if the civilian officer acted in opposition to the health officer and resisted a policy of isolation.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Northern Hospital: Annual Report for 1899.

THE number of patients attended to had been 1795 in-patients and 7411 out patients, involving 26,349 attendances. The hospital contains 155 beds. The ordinary expenditure had been £7305 odd, against £7284 in 1898. There was a balance of £3761 17*s.* 2*d.* due to the bankers of the institution, against £2925 2*s.* 8*d.* in 1898 The outstanding liabilities were £1116 11*s.* 3*d.*, against £945 14*s* 8*d.* in 1898. The receipts from all sources have been £6469 1*s* 8*d* and were derived as follows: legacies, £881 5*s* ; donations, £728 6*s.* 10*d.* ; Hospital Sunday and Saturday Fund, £1638 ; subscriptions, £1858 3*s.* 10*d* ; and other sources, £1363 6*s.* It would have been impossible to have carried on the work that had been done without the Hospital Sunday and Saturday Fund contribution. The new building was nearing completion. One large pavilion and the circular wards were now finished and were partially occupied. The laundry and boiler-house had been in use during the last six months. The other large pavilion had been built and was progressing towards completion. In view of the increased cost of maintenance when the new hospital was completed the committee earnestly appealed to the public for funds. The convalescent fund continued to be of great service. The horse ambulance, now in the charge of the corporation, had been called out 1143 times and was invaluable in cases of serious accidents. The stable accommodation and professional services were still provided by the hospital, hence the committee trust that the former subscriptions to the ambulance fund will be continued. The committee have had to regret the death of Mr. Arthur H Wilson, which occurred in January, 1899 Mr R. W. Murray, honorary surgeon to the Children's Infirmary, was appointed his successor in the post of honorary surgeon.

Report of the Liverpool School of Tropical Diseases.

The first annual report of the Liverpool School of Tropical Diseases deals mainly with the work of the school for 1899. The formation of the school was originally suggested at the annual dinner of the Royal Southern Hospital held on Nov. 12th, 1898. A committee was formed under the chairmanship of Mr. Alfred L. Jones. Mr. William Adamson, President of the Royal Southern Hospital, was appointed vice-chairman (representing together with Mr. A. L Jones the committee of the Royal Southern Hospital), and the following gentlemen were nominated by the public bodies named: Principal Glazebrook and Mr. Charles W. Jones, by the Council of University College; Professor R. W. Boyce and Professor A. M. Paterson, by the Senate of University College; Professor Carter and Dr. Alexander, by the Medical Board of the Royal Southern Hospital; Mr J. O. Strafford and Dr. E. Adam, by the Chamber of Commerce; Mr. C. Booth, jun., and Mr. J. W. Hughes, by the Liverpool Steamship Owners' Association; and Colonel Goffey and Mr. J. Chadwick, by the Liverpool Shipowners' Association Professor Boyce was elected Dean of the School, Mr. J. O. Strafford honorary treasurer, Mr. A. H. Milnes honorary secretary, Major Ronald Ross, late I.M.S., lecturer, and Dr. H. E Annett demonstrator, and the school was formally opened on April 22nd, 1899, by Lord Lister. A subscription list, headed by the chairman with a contribution of £350, to be paid yearly for three years, was opened and the total amount subscribed in 1899, including fees and other items, amounted to over £3000. During the early part of the year Dr. Van Neck, a delegate of the Belgian Government, attended to observe the work for the purpose of reporting to the Minister of Education in Belgium. The year's work consisted of (1) a lecture delivered three, four, and sometimes five times each week by the lecturer on tropical medicine, illustrated by lantern and microscopical demonstrations; (2) clinical instruction in cases of tropical disease at the special ward of the Southern Hospital twice or three times a week by the honorary physicians of the hospital; (3) instructions in special clinical methods in connexion with tropical diseases by the lecturer and demonstrator of tropical medicine; and (4) practical work and demonstrations on the parasitology, bacteriology, and pathology of tropical diseases by the demonstrator at the Thompson-Yates Laboratory, University College. Two special memoirs have been issued by the committee, an account of the first of which will be found in another column. The hospital report shows that in all 176 cases were treated, of which 152 were malarial fever cases, two malarial neuritis, three blackwater fever, five dysentery, three sprue, one diarrhœa, one Malta fever, five beri-beri, two hepatic abscess, one scurvy, and one bilharzia disease. Out of all these only six patients died. The nationalities of the patients were as follows: English, 151; Norwegian, five; German, three; Finnish, three; Swedish, two; Lascar, three; Italian, two; Chinese, two; and American, Dutch, Spanish, Malay, and Austrian one each. The interesting points in connexion with this table are (1) the variety of diseases treated; and (2) the different nationalities of the patients. With more accommodation the list will, no doubt, be largely extended, but as it stands it thoroughly justifies the establishment of a School of Tropical Diseases in Liverpool The most important work of the school was, of course, the malaria expedition to the West Coast of Africa, the members of which were Major R. Ross, late I.M.S., Dr. H. E. Annett, Dr R. Fielding-Ould, Mr. E Austen of the British Museum, and Dr. Van Neck. The work of this expedition was chronicled in our pages at the time and the power of the anopheles to transmit quartan as well as the other fevers was fully demonstrated, thus confirming the results already arrived at by Grassi and Bignami.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary.

ON Jan. 25th a warrant was granted to the managers of the Edinburgh Royal Infirmary by the Edinburgh Dean of Guild Court to erect new pavilions at the Royal Infirmary. These pavilions are to comprise the ear and throat pavilion and the ophthalmological pavilion. They are to be placed on ground partly occupied at present by old houses in Lauriston-lane and partly by the old laundry. The pavilions will lie east and west instead of north and south as do the old pavilions. The ear and throat pavilion will consist of an administrative portion in the centre three storeys high with wings two storeys in height. On the ground floor is a large waiting-room for out-patients with separate entrance, an examination room, an operating room, and a large operating theatre. On the upper floor are two wards to accommodate eight patients each and two wards for two patients. On the attic floor of the central portion are nurses and servants bedrooms, bathrooms, &c The ophthalmological pavilion is to be constructed after a similar plan, but will be somewhat larger, the central portion being four storeys high and the wings three storeys in height The pavilions will be carried out in the same style as the Diamond Jubilee Memorial Pavilion which is now nearing completion All the floors are fire proof, the warming will be carried out by steam pipes and radiators, and the ventilation will be effected by exhaustion by means of electric fans The new pavilions will be connected with each other and also with the main hospital by a light corridor of glass and wood along which food for the patients in the new wards will be conveyed from the main kitchen which is being largely extended to meet the wants of an increased number of patients

Edinburgh Medical Missionary Society

The annual meeting of the Edinburgh Medical Missionary Society was held on Jan 25th The chair was taken by Sir William Muir The report stated that during the year 8752 new cases had been dealt with at the Livingstone Dispensary in the Cowgate Dr Main of Hangchow moved the adoption of the report and was seconded by Dr Laws of Livingstonia

Edinburgh Company Volunteer Medical Staff Corps

The fourteenth annual dinner of the Edinburgh Company Volunteer Medical Staff Corps was held in the Imperial Hotel on Jan 26th, Surgeon Captain Hepburn being in the chair The toast of "The Navy Army, and Reserve Forces was proposed by the Rev G Marjoribanks Stenton and responded to by Colonel J P Rooney, R A M C, and Surgeon Lieutenant-Colonel P A Young, 1st Midlothian Volunteer Artillery The toast of the evening The Volunteer Medical Staff Corps," was proposed by Colonel Rooney and the chairman in acknowledging it said that the company was ' full up '

Proposed Sanatorium for Consumptives at Dundee

At a meeting of the executive committee of the proposed sanatorium for consumptives held at Dundee on Jan 24th it was reported that the best site that could be obtained was on the Auchterhouse estate about two miles from the station and that Lord Airlie had, through Lady Airlie, intimated his resolution to grant the site as a free gift to the city of Dundee The committee accepted the site and passed a hearty vote of thanks to Lord Airlie The site extends to 21 acres and is from 800 to 1000 feet above the sea It is sheltered on all sides and the possibilities as regards water and drainage are satisfactory Ex Provost Moncur, who had presented £10 000 to the committee for the erection of the institution was appointed a trustee together with his son Mr Alexander Moncur

Edinburgh Town Council and Women Sanitary Inspectors

At a meeting of the Edinburgh Town Council on Jan 30th among other matters the council took up consideration of two recommendations of the Public Health Committee under re committed reports, in both of which cases the committee adhered to their former recommendations The one for the addition of four male assistant sanitary inspectors for the sanitary department was agreed to unanimously but the other, for the appointment of two qualified female assistant sanitary inspectors gave rise to a somewhat heated discussion The approval of the latter recommendation was moved by Mr Pollard and seconded by Bailie Brown while Mr Lang Todd, Sir James Russell and Mr Auldjo Jamieson also supported the motion On a vote 21 voted each way and the Lord Provost gave his casting vote against the recommendation

Typhoid Fever Epidemic in Ayr

Fresh cases of typhoid fever continue to be reported in Ayr

The Fife Miners and Medical Fees

There has been some discussion at the various collieries in the county of Fife during the past month as to the rates to be paid for medical attendance At present the rate of contribution in some collieries is 6*d* a fortnight in others only 4*d* From a meeting of the Executive Board of the Fife and Kinross Miners' Association held in December a recommendation was sent out in favour of a uniform deduction of 6*d* a fortnight from the wages At a meeting of the board held at Dunfermline on Jan 17th reports were submitted on the subject and as a considerable diversity of opinion was shown the board decided to leave the matter in the hands of the men to be decided at their respective collieries

Aberdeen Royal Hospital for Sick Children

The ordinary revenue of the Aberdeen Royal Hospital for Sick Children for the 12 months ended Dec 31st last was £1757 19*s* 0½*d* and the ordinary expenditure was £3333 10*s* 6½*d* The number of patients treated in the wards during the year was 758

Death of Dr Henry Jackson of Aberdeen

By the death of Dr Henry Jackson which occurred on Jan 26th Aberdeen has lost one of its oldest and most respected medical practitioners Originally trained as a druggist, Dr Jackson graduated as M D at Marischal College Aberdeen in 1850 and at the time of his death was the oldest member of the Aberdeen Medico Chirurgical Society The deceased was at one time a member of the Aberdeen Police Board and afterwards of the Aberdeen Town Council. He was a total abstainer and was for long a liberal member and office bearer of the Free Church of Scotland He was predeceased by his wife and never had any family

The London Scottish Rifle Volunteers in Aberdeen

The Aberdeen University Corps are to entertain at a smoking concert the detachment of the London Scottish Rifle Volunteers which has just arrived in Aberdeen in order to be affiliated with the Gordon Highlanders previously to their departure for active service in South Africa

IRELAND

(FROM OUR OWN CORRESPONDENTS)

The Health of Dublin

A NOTABLE fall has at last been registered in the death rate of Dublin, the report by the superintendent medical officer of health for the week which ended on Saturday last, Jan 27th being 37 9 per 1000 persons living, The mean death rate in the corresponding period of the previous 10 years was 39 4 per 1000 The zymotic death-rate was 1 5 per 1000, the mean rate for the corresponding week in the previous 10 years being 3 3 per 1000 These figures show that at least relatively and in comparison with other years there has been a notable, if only temporary, improvement in the health of Dublin

The Local Government Act

The Local Government Board have announced that all persons who are paid salaries out of the Poor rate are disqualified from acting as guardians This will exclude the county infirmary officials and the asylum officials

Death of Sir William Miller

Sir William Miller M B Dub J P, High Sheriff for the county and for years mayor of the chief town of Derry, was well known as a physician in large practice and as a public man of whom his fellow citizens felt themselves proud He held the positions of physician to the Londonderry City and County Infirmary and medical attendant to the Londonderry Prison Sir William Miller succumbed to an attack of influenza and died on Jan 29th to the great regret of a very wide circle of friends

The Condition of the Bones in the Insane

A contribution to the pathology of this rather doubtful matter has recently appeared in the evidence given at an inquest held at the Richmond Lunatic Asylum Dublin on Jan 24th in connexion with the death of a female aged 64 years who had been an inmate of the asylum for 39 years She died from bronchitis and heart failure while the post mortem examination showed numerous fractures of the ribs There were indications of nine on the left side and of no less than 21 separate fractures 11 ribs having been broken one in four places one in three and five in two situations Dr Rambaut deposed that the ribs on post mortem examination showed an extreme degree of wasting and were in the highest degree fragile so that they could be easily broken between the finger and thumb and without the crackling which usually accompanies a fracture of bone The bones of the legs and arms were also extremely fragile and could be broken easily with the hands Mr Conolly Norman the medical superintendent of the asylum, gave similar evidence and stated his opinion that the fragility of the bones and the absence of the ordinary signs fully accounted for the fractures not having been detected during life.

Health of Belfast.

The death-rate for the week ending Jan. 20th has been from all causes 24·1 and from the principal zymotic diseases 2·3 per 1000. This is less than the average annual death-rate of the 23 principal urban sanitary districts, which was 31·4 per 1000 during the same time. As it appears that there is a large number of deaths of children under six years of age instructions have been given by the public health committee of the city corporation for returns relating to infant mortality to be prepared and submitted to the committee for consideration at their next meeting.

The Belfast Maternity Hospital.

A sale of work in aid of this charity was held in Belfast on Jan. 25th, which it is hoped will bring a large addition to the funds of a very deserving and necessary institution. The committee are most anxious to start the building of a new hospital, which is necessary alike to the poor women of Belfast and to the medical school, but a delay has arisen as they have discovered that they cannot retain the site of the old one without paying a rent equal to the market value of the land which would now be very high. Several new projects are being considered, but nothing so far is finally settled.

The Belfast Hospital for Sick Children.

At the annual meeting of the friends of this hospital, held on Jan. 26th, it was reported that in 1879 there were treated in the wards 474 children (243 medical, 220 surgical, and 11 eye and ear cases), while in the out-patient rooms 5007 new cases were seen (3011 medical, 828 surgical, 863 eye and ear, and 305 dental cases). Dr. Leathem has been elected on the physicians' side, a vacancy having occurred through the resignation of Dr. F. Howard Sinclair. There is a large clinical class of senior students. New cots have been placed in the surgical ward during the year of the most modern design. Financially there is a deficit of £100 owing to the increase of both intern and extern cases; but the legacies of the year enabled all debts to be paid.

The Samaritan Hospital, Belfast.

The annual meeting of the friends of this hospital was held on Jan. 29th. It was reported that 771 patients had been treated in the extern department and 203 in the wards, and of these 130 were operated on. In spite of the grave nature of these operations (35 were abdominal) the death-rate was under 2¼ per cent. Financially there was a net balance of about £136. A ladies' committee has been formed and has been found most advantageous to the hospital. They have spent a sum of £200 on necessary repairs to the building. The debt at the end of 1898 was £200, which, thanks to the exertions of a member of the ladies' committee (Miss F. Henderson), has been more than paid off. Dr. J. St. Clair Boyd, one of the retiring surgeons, was re-elected.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Victim to Professional Duty.

DR. DEVAY, medical officer in charge of the lunatic asylum which is maintained by the Brothers of Saint-Jean-de-Dieu at Lyons, was recently assassinated by one of the patients. On Jan. 23rd Dr. Devay was vaccinating the paying patients of the institution and while performing this operation a patient struck him a violent blow in the abdomen with some sharp instrument which he had concealed under his clothing. The wound was very severe and the bowel was perforated. Dr. Devay was at once removed to the Hôtel Dieu and Dr. Jaboulay performed a laparotomy, but in spite of all Dr. Devay succumbed to acute peritonitis. Dr. Devay occupied a prominent place among the ranks of specialists in mental diseases and for many years had contributed most valuable papers to the Archives of Neurology, more especially one in 1897 entitled "Melancholia and Exophthalmic Goitre." At the Congress of Alienists and Neurologists of Bordeaux held in 1896 he communicated another very notable paper upon Melancholia in Syphilitics. Besides these occupations he edited with great skill a monthly journal of medicine, the *Echo Medical de Lyon,* which is in its fourth year of public tragic death of so distinguished a professional naturally been the cause of much sorrow amon fession in Lyons.

The Budget of the Assistance Publique.

Dr. Napias, the director of the Assistance P Paris, has just issued the annual report upon th expenses of the organisation for the year 189 expenses, which increase year by year, amount t of 23,033,050 francs. This is equivalent to a sum o for each inhabitant. In 1891 the rate was 7f. 41c., and 5f. 49c. Dr. Napias attributes the increase to the cre new departments and the perfecting of the old ones. statement Dr. Napias counts upon a great augmenta income for the year 1900 owing to a large increase yield from the *droit des pauvres.* These dues enable of 10 per cent. to be levied upon the gross receipts theatres and places of amusement. Taking into conside the number of such places which will be open durin forthcoming exhibition Dr. Napias counts upon a re from this source of 1,500,000 francs in excess of the nary revenue. This estimate, which seems at first enormous, is not really so if the receipts in former exhib years be taken into account. In 1878 the *droit des pau* realised 3,906,342 francs, whereas in the preceding the figures were 2,728,154. In 1889 the assets were 4,438, francs and in the preceding year 3,023,430, showing difference of 1,414,712 francs. Even if there be allow a sum of 30,000 francs for increased expenditure during t period, as Dr. Napias assumes, it will be seen that t increase which he hopes for is by no means unreasonabl although there will no doubt be increased expenses owing the strain which will be thrown upon the hospitals.

Dissensions between Medical Men.

An unfortunate state of matters has arisen between the medical man in charge at the Blind Children's Institute and his second in command. As a rule, when there is a chief and a second in command the latter succeeds to the post of the former at his death or his resignation. But at the Blind Children's Institute there seems to be a tradition that the senior post should be farmed by members of the same family without any consideration for the rights of the assistant medical officer. In 1872 Dr. Lombard, the senior medical officer, resigned in favour of his son-in-law, Dr. Claisse. Dr. Brognard, the junior medical officer, being left out in the cold, resigned. In 1898 Dr. Claisse resigned, nominating as his successor his son, Dr. Paul Claisse, without regarding the claim of his junior, Dr. Watelet, although the latter was an elderly man and well known, while Dr. Paul Claisse is but 33 years of age. Dr. Watelet protested against this arrangement, and it was determined, with the concurrence of Dr. Paul Claisse, to submit the matter to the arbitrament of the medical men of the Seine. These gentlemen decided against Dr. Paul Claisse and in favour of Dr. Watelet. Dr. P. Claisse, however, in spite of this opinion stuck to his post. Dr. Watelet wrote him a letter marked "personal and private," in which he reproached him for his action in not abiding by the result of an arbitration accepted by him. Dr. Claisse thereupon sent this letter to the Minister of the Interior, M. Waldeck Rousseau, with an intimation that he took it as an act of insubordination on the part of the junior medical officer. M. Waldeck Rousseau has just intimated to Dr. Watelet, who is able to count 30 years' service, that he must apologise to Dr. Claisse or resign. This unfortunate incident, which is the subject of much comment in the public press, has made a great sensation in Paris.

Reform in the Provision for Medico-Legal Expert Evidence.

At a recent meeting of the Forensic Medical Society the introduction of an amendment to the new law concerning expert evidence was discussed on the motion of M. Jacomy. The society considered that the words "*expertise contradictoire*" should be expunged from the text of the regulations as defective and leading to misunderstanding. The chief part of the discussion was, however, taken up in considering the length of time allowed to the accused for making up his mind as to the choice of an expert witness. M. Jacomy considered that the period of three days allowed to the accused — which were in reality five days, viz., three days in which to make up his mind, one day to notify his choice to the judge, and one day for the notification of the expert chosen by the judge to the accused—was much too long for at an interval of five days after death expert evidence was not of any use. M Jacomy considered that the examining magistrate should be empowered to nominate a provisional expert on behalf of the accused as soon as he should signify his choice after consultation with his solicitor. Professor Brouardel laid great stress upon the necessity for making expert examinations at as early a date as possible, for the earlier they were made the more valuable they were Especially was this the case in the country where there was a lack of freezing apparatus, and in such circumstances bodies were almost always in a state of decomposition by the time they were submitted to the expert It is almost impossible to make satisfactory expert examinations from June to October. Even in Paris 48 hours generally elapsed before any examination could be made, and if a second expert were necessary who could not begin his work before the lapse of five days expert evidence would be an impossibility. In the interests of justice the choice of a second expert should be made within 24 hours After a very interesting debate the above conclusions were unanimously agreed to.

The Sale of Secret Preparations

A BILL relating to the sale of secret preparations is being introduced by the German Government According to the *Pharmaceutische Zeitung* its principal provisions will be as follows The central authorities of each State of the empire shall register the medicinal compounds which are to be regarded as of secret composition Substances which are contained in the German Pharmacopœia or are generally recognised as remedies by medical science, or are intended only for disinfectants or cosmetics, however, may be sold without registration The public advertisement of medicines of secret composition is prohibited. The bottles, boxes, &c, must bear only the name of the compound, the name of the maker, and the price. It is strictly prohibited to affix to the bottles or boxes labels containing recommendations, professional opinions, expressions of thanks by patients, or any other statement by which a special action of the compound is announced Licensed druggists may sell secret preparations only on the written prescription of a medical man The sale of secret preparations which are prejudicial to health is prohibited The medical journals generally are in favour of the new Bill; they recommend, however, that the registration of secret preparations should be undertaken not by the individual States of the empire but by the Imperial Health Office for the whole territory of the empire so as to avoid the anomaly that a compound may be regarded as a secret preparation in one place whilst it may be sold without restriction in a neighbouring town belonging to another State.

Medical Journals in Germany

The Berlin medical press has been increased by the issue of a new periodical entitled *Die Medicinische Woche* (*The Medical Week*), which is to appear every Monday The editor is Dr. Paul Meissner of Berlin The first number contains a leading article by the editor, an address by Professor von Bergmann on first-aid service, original articles by Professor Brieger and Dr. Friedjung, together with other matter consisting of reports of meetings of medical societies in Berlin and abroad, reviews of books, and other miscellaneous subjects The number of medical journals has greatly increased of late years Apart from the surgical, obstetrical, and other specialist weekly, fortnightly, or monthly periodicals, there are now many journals dealing with medicine and professional matters Up to 1864 there was only one journal of this kind, the *Allgemeine Medicinische Central Zeitung*, which still continues to appear and is now in its sixty-eighth year. In 1864 the *Berliner Klinische Wochenschrift* was founded by Dr. L Posner, the father of the present co-editor, Professor C Posner This was the first important medical journal in Berlin and was the only one till 1875, when the late Dr Borner founded the *Deutsche Medicinische Wochenschrift*, which was afterwards edited by Dr Gutmann, the present editors are Professor Eulenburg and Dr. Julius Schwalbe The two last mentioned periodicals are the leading medical journals of Berlin, and together with the *Münchener Medicinische Wochenschrift* are the leading medical journals of Germany, occupying a position in this country equivalent to that of THE LANCET and the *British Medical Journal* in England. A few months ago a similar journal called the *Deutsche Aerzte Zeitung* appeared under the editorship of Professor Stadelmann, it is somewhat smaller and therefore cheaper than those above mentioned Another paper containing fewer original articles but devoting much attention to reports and reviews of books, German and foreign literature, and medical societies is the *Deutsche Medicinal Zeitung* conducted by Dr. Grosser The contents of all these medical weekly papers are almost exclusively scientific, and, contrary to the customs of the British medical press, the space allotted to the social and economical interests of the profession is relatively small On the other hand, there are a number of papers which are devoted exclusively to professional as distinguished from scientific matters Most of them are distributed free of charge to the Berlin practitioners either because they derive their income from advertisements or because they are supported by professional societies To the latter class belong the *Berliner Aerzte Correspondenz*, the organ of the Berliner Standesvereine, edited by Dr Joachim, the *Medicinische Reform*, the official organ of the Free-choice Society the *Deutsche Medicinische Presse*, and others The *Aerztliches Vereinsblatt*, which is the official organ of the German Practitioners' Association, and the *Aerztlicher Central-Anzeiger*, which is specially devoted to the interests of country practitioners, are edited not in Berlin but in Hamburg.

ROME.

(FROM OUR OWN CORRESPONDENT)

A Congress of International Hygiene.

THE invitation addressed to the European Governments by their Italian sister "to give an opinion as to the opportuneness and advisability of convening a Congress of International Hygiene similar to that held at Venice in 1897, to take measures for the defence of Europe against the pestis bubonica," seems, according to information derived from the Consulta (the Foreign Office), to have elicited replies favourable to such a project From the same source I learn that the Italian Government has had quite sufficient encouragement from the Powers to employ itself in formulating a "questionario" or schedule of debateable points in view of the Congress becoming a *fait accompli* Among these points the chief, I understand, are quarantine, and the rules to be enforced against the diffusion of plague or contagious maladies capable of assuming an epidemic form. Minor points for the consideration of the Congress are said to be "il commercio delle specialità medicinali, delle acque minerali, e degli altri articoli farmaceutici" (the trade in medicines of a special kind, in mineral waters, and in other articles sold by pharmaceutical chemists) On the completion and distribution of the "questionario" the Italian Government will next propose to the Powers the place at which the Congress shall meet and the time at which to hold it This latter detail will, as THE LANCET[1] has abundantly shown, be the most difficult to settle The tension between several of the great Powers is at present too severe to conduce to amicable discussion of such topics as "international sanitation" These, as late events have shown, may be highly debateable—even the organisation of the Red Cross having had to lay its account with the susceptibilities of Powers more or less closely identified with alliances "dual" or "triple" Postponement to a season when the political atmosphere is less charged with explosive element is, as THE LANCET suggested, the course least open to difficulty in convening the proposed Congress; and, indeed, it is significant that in their replies to the Italian invitation the sister Powers, while unanimous as to the "advisability" of holding some such meeting, appear to be, one and all, silent as to its "opportuneness."

Influenza

Not only epidemic but pandemic, influenza is master of the situation Nearly every public interest or occupation has to pay tribute to it. Indeed, the more numerous the *personnel* employed the greater the number of its victims. True, the inmates of monasteries, or prisons, where a simple, austere life is the rule, are singularly free from it; but once let an infected individual find entrance into these communities and it passes from inmate to inmate till two-thirds or three-fourths of them are attacked. The two facts were noted by the Italian profession centuries ago. Lancisi, for example, the Pope's physician, remarked in 1709 when influenza prevailed in Rome that the prisoners *of the Holy Inquisition were untouched by it.* On the other hand, Mercuriali in 1580 observed that once an infected case found admission into a community or family the malady *diffused* itself rapidly. "*Mirum est*," he says, "*ubi unus* corripitur aliquã in domo, statim singulis ejus familiæ malum communicari" (It is remarkable when one person in any household is attacked that forthwith the disease is communicated to the other individuals composing it). The bacillus lurks in the mucosa of the air passages, so that the breath and still more the bronchial secretion and sputa of the patient are perhaps the most prolific source of its multiplication and spread. In Italy the churches, open all day and frequented by the very poor, who never use pockethandkerchiefs, have their pavements converted into "influenza preserves"—the desiccated sputum parting with its bacilli every time a current of wind comes through the door, till the said bacilli load the air and impregnate the *bénitiers* or fonts of holy water with which the devout daub their faces. These are facts which the "*Uffizi d'Igiene*" *of municipalities* are now thoroughly alive to, with the result that, wherever practicable, expectoration on floor or pavement *is* prohibited, sometimes under penalties. Meanwhile the prevalence of the disease is, as the health officers throughout Italy are reporting, "assai inquietante" (very alarming). In Rome there are over 40,000 cases under treatment and possibly as many more among the very poor unknown to the profession. Coincident with the severe, prolonged winter, the virulence of the malady is at its worst in Northern Italy—in Turin, for instance, the "tavole necrologiche" registering 73 deaths in the 24 hours. This mortality is even higher than that of the epidemics of 1889-90 and 1891-92 when influenza, with its peculiarly "neurotic note," decimated the Subalpine capital. At the Vatican the vigilance of the Pope's body physician is, if possible, redoubled, and the utmost care is practised so as never to let the temperature of the apartments frequented by His Holiness fall below 65° F. Of the three patients mentioned in THE LANCET of Jan. 20th (p. 205) Cardinal Trombetta is dead; Prince Altieri, commandant of the pontifical guard, is also dead; and the Cardinal Vicar (Jacobini) has received the last consolations of the Church and is *in extremis*. On the other hand the Minister of Public Instruction (Dr. Baccelli) is now convalescent and is shortly expected at Genoa on business connected with his portfolio.

Jan. 30th.

RUSSIA.

(FROM A CORRESPONDENT.)

Another Outbreak of Plague in Southern Russia.

NEWS has just been published of the occurrence, in the second half of November, of yet another outbreak of plague in Russia. The facts now made public are scanty, but though the assertion is not definitely made that the disease in question was in truth plague it is scarcely possible to doubt that it was so. The symptoms appear to have resembled in every respect those of the outbreak at Kolobovka on the Volga last summer, and, moreover, the disease proved fatal to every person attacked by it. The scene of the late outbreak was two Kirghiz *aouls*, or encampments, in the maritime division of the Krasnoyarsk *uyezd*, or district, in the Government of Astrakhan. As the town of Krasnoyarsk, which gives its name to the district, is situated on one of the mouths of the Volga river quite close to the village of Kolobovka it would appear that the scene of the late outbreak was at no great distance from that of last summer's epidemic. The *aouls* in question are situated on an island, and as exceedingly stormy weather prevailed at the time of the outbreak the inhabitants were unable to communicate with the shore. It was only at the end of November (according to the Old Style which is 12 days posterior to the western mode of reckoning), when the waters froze, that communication with the shore was re-established and the authorities came to hear of the epidemic. The names of the *aouls* were Kishkine-Aral and Kine-Aral. The symptoms of the disease were described as consisting of fever, headache, pain over the heart, and expectoration of blood. As soon as the Governor of Astrakhan learnt of the outbreak he telegraphed the news to the Imperial Plague Commission, and at the request of the Commission he at once personally visited the island. The most radical measures of disinfection and destruction of infective material were put in force. Not only infected articles which had belonged to those who died from the disease, but the tents themselves, were *burnt*. The sick were *isolated* and the other inhabitants were first given a bath, then provided with new clothes, and put into clean tents at a distance from the old ones and kept under supervision by medical men. By Dec. 5th (17th) the outbreak was at an end; but not until 59 persons had succumbed to the disease. As already stated not a single patient recovered, and the case-mortality was consequently cent. per cent. The epidemic was therefore a considerably more extensive one, and even more fatal, than that at Kolobovka, where 24 persons were attacked and one did recover. From the brief summary of the symptoms and from the extremely high mortality it can scarcely be doubted that the later outbreak, as the earlier one, was one of the pneumonic form of plague. Some further light upon its character will probably be thrown by the inquiries of Professor Levin, Professor Raptchevski and Professor Vinogradof, who have been sent by the Imperial Plague Commission to investigate the outbreak. Their report will be looked forward to with interest.

Recent Prevalence of Diphtheria in Russia.

Diphtheria has for some years past been one of the most widespread and fatal of all zymotic diseases in Russia. Dr. *Rankhfus*, a leading authority upon all diseases of childhood, read a valuable paper upon the subject before a medical society in St. Petersburg in March of last year. That paper has just been published in full in *Botkin's Hospital Gazette.* As an epidemiological and therapeutical study of the recent prevalence of this disease Dr. Rankhfus's essay is a model, and it is regrettable that it is not possible here to do more than summarise the conclusions at which he arrives. Those conclusions are briefly as follows: 1. The present epidemic of diphtheria in St. Petersburg dates since the year 1894, and is part of a pandemic of the disease which has affected a great portion of the Russian Empire. 2. The preceding epidemic of diphtheria in St. Petersburg was in the years 1881 to 1884 inclusive. It affected probably fewer persons than the present epidemic, but, on the other hand, the case-mortality was then nearly twice as high as it is now. The change from high to low case-mortality did not occur at the beginning of the present epidemic, but came on suddenly and exactly at the time of the introduction of the serum treatment—that is to say, in the second year of the epidemic. 3. The case-mortality from diphtheria in the Prince Peter of Oldenburg's Children's Hospital—the principal hospital of the kind in St. Petersburg—was during the 25 years 1870-1894 on an average 54 per cent. The maximum had been 60·6 and the minimum 46·2 per cent. From 1870-1880, a period when the disease was not epidemic, the average mortality was 52 per cent.; in 1881-1884, an epidemic period, it was 59 per cent.; and in 1885-1894, a non-epidemic period, it was 55·8 per cent. The case-mortality was, therefore, not very materially affected by the degree of prevalence of the disease. In 1894 the case-mortality was as high as ever. But in 1895, when the serum treatment began to be widely practised, there was a sudden fall in the mortality to 23·9 per cent., and since that year it has varied between 21·4 and 25·5 per cent. 4. The character of the recent epidemic has not been the same throughout. In the last two years (1897-1898) the number of cases of phlegmonous (septic) diphtheria has largely increased, and the number of cases of diphtheritic croup has correspondingly diminished, in comparison with the numbers of each class in the first two years (1895-1896), and at the same time the phlegmonous cases have become more malignant in character. 5. The same reduction in case-mortality since the introduction of the serum treatment has also been observed in the other children's hospitals in St. Petersburg. The remaining conclusions deal in detail with the different types of the disease and the effect of the serum treatment upon them. It was fo the mortality in cases of diphtheritic croup to a greater extent than in cases of phlegmonous or septic diphtheria Excluding those cases which died within 24 hours of admission to hospital the mortality in patients treated with the serum was only 19 6 per cent, while in those not so treated it was 39 6 per cent, or almost exactly double Finally, Dr Rankhfus concludes that in the anti diphtheritic serum we possess the most powerful remedy for the disease which has hitherto been discovered

New Style and Old Style

No little confusion arises at times from the retention in Eastern Europe of the Julian calendar and the constant necessity of indicating whenever a date is mentioned whether that date is according to the New Style or according to the Old Style A commission is already sitting in Russia to consider the advisability of doing away with this discrepancy, and it may be hoped that it will be found practicable to introduce the New Style and so (should Greece follow suit) make the dates the same all over Europe The difference between the two styles is now 12 days, but in another month it will be 13 days as this year is not a leap year according to the Gregorian calendar, while it is one according to the Julian calendar Up to two centuries ago the date of the year was reckoned in Russia as from the creation of the world The year 1699 was called the year "7208 from the creation of the world" (*ot} sotrorénia mira*) and it was only in that year that the western mode of reckoning from the birth of Christ was introduced The change was made by Peter the Great in an ukase dated Dec 19th 1699, and at the same time the beginning of the year was altered from September 1st to Jan 1st The new mode of reckoning was not, however, made compulsory, and it was permitted to use either the date *Anno Domini* or the date "from the creation of the world" or both together On the day following the issue of this ukase another was published announcing the commencement of a new century on Jan 1st 1700 Moscow was *en fete* for a whole week, guns were fired, and the city was illuminated in honour of the event This imperial method of settling a highly controversial question—of which a recent and exactly parallel instance will be fresh in every one's mind—has not a little to commend it

Obituary.

SIR WILLIAM MILLER, M B T C D, J P

THE death is announced of Sir William Miller—one of the most respected and able practitioners in Ulster—after a short illness at his suburban residence Braehead, Londonderry on Jan 28th, at the advanced age of 73 years He had been attending to his usual duties until he was attacked by influenza Sir W Miller was the second son of the late Joseph Ewing Miller M D, J P a medical man who several times during his long life of 92 years had held the office of Mayor of Derry Born in Derry young Miller studied in Trinity College, Dublin where he graduated M B in 1853 becoming a Licentiate of the Royal College of Surgeons in Ireland in the same year Returning to his native city Dr Miller began practice and followed his father's footsteps in taking an active part in public life there For 40 years he held a prominent professional and social position in Derry He was a magistrate of the city and of the county of Derry and a grand juror of the county In the year 1875 he was chosen mayor of the city of Derry and on that occasion he entertained the Lord Lieutenant of Ireland (the Duke of Abercorn) and the members of the Royal Agricultural Society who visited the city during his year of office He was re elected mayor the following year and was then knighted and was again chosen chief magistrate for the third year in succession He also was elected mayor in 1888 and in 1889 He gave a great portion of his time to the administration of public affairs of the city and county of Derry and he had just been appointed high sheriff of the county for the present year Professionally he had a large private and consulting practice He held all the best medical appointments being surgeon to the County Derry Infirmary, medical officer to the County Derry Gaol and Londonderry Post Office physician to the County of Derry Fever Hospital and Surgeon Major of the Londonderry Artillery Militia He was also a member of the Londonderry Bridge Board It is given to few men in any profession to attain such a distinguished public position in his native city as fell to the lot of Sir W Miller He was a level headed Ulsterman of great prudence, caution, and sagacity and it was these qualities of head as well as his kindly disposition which gave him such a commanding civic and professional position He has left a widow and a large family Two of his sons occupy prominent positions in Derry, one of them (Dr Joseph Miller) being in the medical and the other in the legal profession

ALEXANDER CHARLES ARCHIBALD ALEXANDER OF BOYDSTONE, B A CANTAB, M R C S ENG, L S A, MAJOR R A M C.

THE death of Major A C A Alexander, R A M C, of the Coldstream Guards who was recently permanent medical officer to the Royal Military Tournament, which occurred on Jan 23rd has occasioned great regret to a wide circle of friends Major Alexander was educated at Cheltenham and Trinity College Cambridge On obtaining his degree in Arts he entered the medical school of St George's Hospital After qualifying as M R C S Eng he obtained a commission in the 3rd Battalion of the Royal Scots Fusiliers He served later in the 1st Battalion Coldstream Guards, which regiment he accompanied in the Suakim Expedition in 1885, and was present at the engagements at Hasheen at that near Tofrek, and at the destruction of Tamai for which services he obtained the medal with clasp and the Khedive's star Last year he returned from Gibraltar on sick leave having had a slight sunstroke, from which unfortunately he did not entirely recover so that to his great grief he was unable to accompany his regiment on the present South African campaign

Major Alexander succeeded to the estate of Boydstone on the death of his father some twelve years ago He was a justice of the peace for the counties of Ayr and Lanark, in each of which he owned property He was a man of splendid physique and in the prime of life and his many friends in the service in the medical profession, and in society generally will find it hard to credit that death has seized upon so vigorous a man, who seemed to have before him a long and useful life

THOMAS JONES DYKE J P, F R C S ENG, L S A.

WE have to record the death on Jan 20th, at the advanced age of 84 years, of Mr Thomas Jones Dyke who had held the position of medical officer of health of the town of Merthyr for over 36 years He was articled at the age of 15 years to Mr David Davies who was then surgeon to the Cyfarthfa Iron and Coal Works, Merthyr and at the end of three years he entered as a student at Granger's School in the Borough He took his L S A in 1837 and his M R C S in the year following In 1866 he was elected a Fellow of the College The Public Health Act 1848 gave permissive authority to local boards of health to appoint a fit and proper person to act as officer of health to the district, but it was not until 1872 that such an appointment was made obligatory upon sanitary authorities From the days of the Health of Towns Commission Mr Thomas Jones Dyke became an enthusiastic sanitarian and by means of public lectures he succeeded in bringing home to his fellow townsmen in Merthyr such a sense of their responsibilities in public health matters that in the year 1849 it was decided to form a local board of health Throughout the cholera epidemics of 1849 and 1854 Mr Dyke acted as medical officer to the board of guardians In the former year there were nearly 1700 fatal cases and he himself was attacked by the malady In 1863—nine years before the appointment was made compulsory—he was elected medical officer of health to the local board at the modest salary of 20 guineas per annum and in 1873 he was appointed to a similar office by the Merthyr Rural Sanitary Authority, continuing an official under both bodies under their altered titles, until the day of his death During the last six years he had retired altogether from general practice and devoted himself entirely to his public health duties

Mr Dyke was a Fellow of the Incorporated Society of

Medical Officers of Health and of the Sanitary Institute and a Member of the Société Française d'Hygiène. He was a Justice of the Peace for the county of Glamorgan and in 1876 and 1877 held the office of high constable of Merthyr. He was the oldest Freemason in Wales, having been initiated in the Loyal Cambrian Lodge, No. 110, in the year 1839, acting as secretary of the lodge for 20 years. In the Provincial Grand Lodge of South Wales and Monmouthshire he had filled the office of grand senior warden.

FREDERICK EDWARD PEARSE, M.D. St. And., M.R.C.P. Edin., M.R.C.S. Eng.

At the meeting of the Frome Board of Guardians held on Jan. 23rd a vote of condolence was passed with the family of the late Dr. Frederick Edward Pearse who had been medical officer and public vaccinator for the first district of the Frome Union for the past 18 years and had previously held the appointment of medical officer of health of Wellington.

Walton Convalescent Home, near Clevedon.—The annual report shows that 431 patients (158 males and 273 females) were admitted during 1899.

University College of North Wales.—At a meeting of the Court of Governors of the University College of North Wales held at Bangor on Jan. 22nd it was decided to construct new college buildings in Bangor.

Clevedon Convalescent Home.—The annual report for 1899 states that 396 patients were admitted during the year (175 men and 221 women). The authorities of the home have offered 24 beds for the reception of wounded soldiers and this has been accepted.

Vaccination Returns.—At a meeting of the Calne (Wilts) Board of Guardians held on Jan. 23rd it was reported that during the year ended Dec. 31st the births of 171 children were registered, of whom 36 were vaccinated, nine were exempted, 15 died, and 111 remained unvaccinated.

Hospital Saturday Fund.—At a special meeting of the board of delegates of this fund held at the offices, Gray's Inn-road, on Saturday, Jan. 27th, on the recommendation of the distribution committee a sum of £17,013 was awarded to the 174 participating institutions and £2938 to 27 miscellaneous institutions, including ambulance, distribution, and surgical appliance committees, and institutions for the gratuitous nursing of the sick poor in their own homes. The total receipts for 1899 were £20,023, an increase of £684 upon the previous year, but the awards were less.

Presentations to Medical Men.—Mr. James Carlisle, L.F.P.S. Glasg., of Crossgar, co. Down, and his wife have been the recipients from friends, on their leaving Crossgar, of an address and a drawing-room clock and ornaments as tokens of esteem and regard.—On retiring from the post of acting medical superintendent at the Grove Hospital of the Metropolitan Asylums Board Mr. F. Foord Caiger, M.D. Lond., has been presented by the medical staff, the matron, nursing staff, [illegible] employées in the domestic service with a silver [illegible] case, a chased silver cake-basket, and [illegible] sugar caster as marks of regard and friendship.—[illegible] well-attended meeting at the Coöperative Hall, N[illegible] on Jan. 25th, Mr. John Sutherland, M.B., C.M. Edin., B.Sc., after six years' residence in that village, was presented with a silver tea and coffee service on the occasion of his recent marriage. The Vicar, in making the presentation on behalf of the subscribers, concluded his remarks by wishing that Dr. Sutherland might have happiness and prosperity and that it would be many years ere he ceased to administer to their ailments.

University of Cambridge.—An Allen Scholarship of the value of £250 for one year will be awarded this term for research in medicine, mathematics, physics and chemistry, biology and geology, or moral science. Candidates must be graduates under 28 years of age at the beginning of this year and must undertake to devote themselves to research in the subject of their choice in Cambridge or elsewhere. Applications are to be sent to the Vice-Chancellor on or before Feb. 20th.—The Faculty of Medicine of University College, Cardiff, has been recognised by the university for the purposes of medical study.—The Botanical School buildings have presented plans and estimates for the new laboratories to be erected on the ground recently purchased from Downing College. The buildings will cost about £22,500 and will meet the present and prospective requirements of the department, which has long suffered from overcrowding. The source of the necessary funds is less apparent, though doubtless the recent benefactions to the University will be drawn upon to some extent.—Lord Lister has been appointed an elector to the professorship of Pathology in the place of the late Sir James Paget.—Dr. Henry Jackson has been elected without opposition to the place on the council of the Senate vacated by Mr. Dale, now principal of University College, Liverpool.—By a very large majority the Governors of Addenbrooke's Hospital have adopted a scheme whereby the University Medical School shall be brought into closer relations with the hospital. In consideration of an annual subsidy of £300 the governors will elect the Regius Professor of Physic and

Professor of Surgery to the staff of the hospital, and will provide all needful facilities for clinical instruction and examinations

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Opening of the Session

THE Seventh Session of the present Parliament was opened on Tuesday, Jan 30th, when a message from Her Majesty the Queen was read in the House of Lords by the Lord Chancellor, acting as one of Her Majesty's commissioners In this message Her Majesty spoke of the heroism shown by her soldiers and sailors in South Africa, and expressed her regret that so many valuable lives should have been sacrificed, and said, "*I am confident that I shall not look to them* in vain when I exhort them to sustain and renew their exertions until they have brought this struggle for the maintenance of the empire and the assertion of its supremacy in South Africa to a victorious conclusion With regard to India Her Majesty said, 'I regret that owing to insufficient rainfall in the autumn over a great part of Western and Central India, the harvests and pasturage have failed to such an extent as to create a famine Timely measures have been taken by my *Government* and by the rulers of the Native States affected to relieve suffering and to prevent starvation I regret to add that the epidemic of plague continues and that although its severity has not increased since last year there is at present no prospect of its diminution' The references in the *message to intended* legislation were not numerous *nor* were they of very great importance Mention was made of Bills to amend the law of lunacy factory legislation, the Housing of the Working Classes Act and the Companies Acts, and to lessen the number of accidents among railway servants The Bill for the Amendment of the Companies Acts will, in all probability, contain a provision with reference to companies carrying on medical practice There was no mention in the message of any Bill to amend the Medical *Acts* but *it does not follow that such a measure will not be introduced* by the Government in the course of the session

The London Water Question,

The final report of the Royal Commission appointed to inquire into the subject of the water supply within the limits of the metropolitan *water companies has been* laid on the table of Parliament.

Special Rules for Chemical Works and Match Factories

The Secretary of State has prepared two new sets of special rules—one in regard to the employment of persons in chemical works in which is carried on the manufacture of bichromate or chromate of potassium or sodium, and the other in regard to the employment of persons in lucifer match factories in which white or yellow phosphorus is used

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PROPERTY IN A PRESCRIPTION.

AN amicable dispute illustrating one side of the question that is often asked: To whom does a prescription belong? is placed before us in the following letter Our comments are based, of course, upon the letter which has been written by the patient, but with the facts in which we presume the medical man agrees.

To the Editors of THE LANCET.

SIRS,—Will you kindly say in an early number of THE LANCET who is right under the following circumstances? A patient who has been attended for an illness for some time by a doctor in general practice expresses a wish to see a consulting physician and does so accompanied by the general practitioner (hereinafter called "the doctor) The consultant having heard all about the case and examined the patient, says to the doctor, "What medicine have you been giving him?" The doctor tells him and the consultant then says, "Very well, he can go on with it," or words to that effect. Now, had the patient gone to the consultant alone he would have had a prescription from him, and he contends that he is entitled to ask the doctor for the one of which the consultant approved and therefore practically prescribed, as otherwise he is worse off by taking his doctor with him than if he had gone alone, and except a general opinion gets nothing for his fee The doctor contends that the patient is not so entitled Which is right, both in the legal and professional aspects of the case? The doctor and his patient are perfectly friendly in the matter and only want what is proper, but each entertains a strong opinion on the point. The patient goes about a good deal from place to place The patient could, of course, at any time pay the consultant a second visit and fee unaccompanied by the doctor and so obtain the prescription he wants, but this would only put him to unnecessary trouble and expense without in any way benefiting the doctor

I enclose my card and remain, Sirs, yours obediently,

PATIENT.

"Patient's" letter touches upon several interesting points We do not attempt to give an opinion upon the legal aspects of the case—it is not within our scope to do so—and we cannot more than guess what would be the decisions of judges upon the question of to whom the copyright in a prescription belongs Sophistry, we imagine, could make out an excellent claim on either side. "Patient" does not bring any good arguments to bear to support his claim He had no right to assume that he would get a prescription *from* the consulting physician as the result of consulting him What he would certainly get would be consideration of his case and recommendations as to treatment, but it was not inevitable that he should receive a prescription Nor is his view of the value of a prescription a sound one though it is a common one "Patient" should remember that a *prescription* is only given to meet the existing conditions when the sufferer comes under the physician's eye It is not a formula to be kept in his desk so that he can get it made up at a druggist s whenever he thinks that the remedy will suit his physical ills nor is it intended that he should recommend it to his friends for the alleviation of troubles which he or they may think resemble the troubles for which medical advice was originally given. A prescription is designed purely to meet temporary circumstances it is to be taken for such a time as the prescriber thinks desirable and no longer without a renewal of his authority So that "Patient cannot maintain that he sustains any *loss* by not being in a *position to* use it for other than temporary purposes Some medical men recognise this temporary character of their prescriptions more decidedly than others, and in writing their prescriptions indicate that after such and such a date the formula is not to be used without their written sanction, a proviso to which every good druggist would attend implicitly "The patient goes about a good deal from place to place," says our correspondent, and this seems to imply that he will find it inconvenient to consult his medical man every time that he wants medicine, hence, probably, he wishes to have the prescription that he may drug himself as occasion arises It is well, from a medical point of view, that he should not be in a position to do this

Two other points in "Patient s" letter call for notice. Firstly, he feels that he has not had his money s worth because he is deprived of a chance of getting unlimited medicine. He evidently regards the medicine as the thing and not the diagnosis or the general plan of treatment. Secondly, he speaks of the situation that would have arisen if he had placed himself under a consultant physician directly, having clearly no idea of the position which the consultant physician is supposed to occupy towards the general practitioner It is distinctly unprofessional of any consultant physician to take over the care of a general practitioner s patient, and before "Patient" could have obtained from the consultant the assistance he desired he would have had to conceal the fact that his medical man was already treating him.

"IMPROPER ADVERTISEMENT."

REFERRING to the letters which appeared under this heading in our issues of Dec 23rd, 1899, p 1790, and Dec 30th, 1899, p. 1870, we desire to say that we unreservedly accept the statements in Dr Fürth s letter of Dec 26th, 1899, and published in our issue of Dec, 30th, 1899, and to express our regret that a letter which imputed improper advertising to Dr Furth should have been allowed to appear in these columns.

"THE VOMITING OF PREGNANCY"

To the Editors of THE LANCET.

SIRS,—"Obstet," in THE LANCET of Jan 20th, 1900, p 212, asks a question which requires a very long reply, but if he will glance at Sections 860 and 861 of the Medical Digest he will find all he needs in the two columns of remedies A mixture that has been found efficacious in most cases is as follows: two drachms of bromide of potassium, half a drachm of liquor strychnia, and three ounces of chloroform water, one-twelfth part to be taken in water three or four times a day.

I am, Sirs, yours faithfully,

RICHARD NEALE, M D Lond.

Finchley road, Hampstead, N W, Jan 25th, 1900

"THE MOTHER S CALL"

WE have been informed that the following stirring verses which appear in the *Wellington Evening Post* are from the pen of a medical man, and that the initials stand for the name of Dr G E Anson of Wellington, N Z —

I

What whisper this which ripples round the world,
  And stirs the Viking pulses in our veins?
Ten thousand flags of Liberty unfurl'd!
  Ten thousand dreams of battle in our brains!

CHORUS—

'Tis the Nation mother whisp ring 'neath the waves,
Calling for her children, calling on her braves!
  O, mother who has bred us,
  Protected us and led us,
We are coming, coming, coming o'er the waves!

II

Bleeding she grips, nor counts the cost or time;
  While envious nations stand around and jeer!
Shall we, the pampered darlings of her prime,
  Craven, ungrateful, deem the price too dear?

CHORUS—'Tis the Nation-mother &c., &c

III

The Sumac, and the Maple, and the Pine,
  The Rata, and the Wattle and the Gum,
All bow their heads together at the sign,
  And chorus back —"O, mother, we will come!"

CHORUS—'Tis the Nation mother, &c., &c

IV.

We reck not of the traitor's poison'd lie,
  Nor sharp-tongued arrows of the fickle press,
Sure of the Right, we hear thy Mother-cry,
  And give our lives to thee! We give no less!

CHORUS—

'Tis the Nation mother whisp'ring 'neath the waves
Calling for her children, calling on her braves!
  O, mother who hast bred us,
  Protected us and led us,
We are coming coming, coming o er the waves!

"THE CHAIRMAN'S HANDBOOK."

To the Editors of THE LANCET

SIRS —Can you or any of your readers recommend a small book as guide to a chairman s conduct at a meeting? I believe there is such a book called "The Chairman s Handbook."

I am, Sirs, yours faithfully

Jan 27th, 1900. M D

*** "The Chairman's Handbook," by Sir Reginald Palgrave (Sampson Low, Marston, and Co) 2s —ED. L.

"THE DEARTH OF QUALIFIED ASSISTANTS"

To the Editors of THE LANCET.

SIRS,—With respect to your remarks *re* the dearth of locum-tenents I cannot think that the suggestion of "Unqualified" in THE LANCET of Jan 20th will solve the difficulty I am not sufficiently learned in political economy to know whether in the event of the demands exceeding the supply the locum tenent is justified in attempting to raise his market value, though it appears to me that it is a general consequence in the commercial world, and that for much the same reason the salary of the permanent assistant has been advanced about 30 per cent during the last 18 months I have noticed that in the past there has been a marked tendency manifested to obtain a locum tenent below the usual market rates, which I take to be three guineas per week and travelling expenses. If this tendency was the result of the employment of the unqualified assistant, who, doubtless on occasion, assumed the rôle of locum tenent, it is hardly to be wondered at if, now that the iniquity of allowing the unqualified to

Presidential Address

ON

THE PRESENT POSITION OF AURAL SURGERY

Delivered at the First Meeting of the Otological Society of the United Kingdom on Feb 5th 1900,

By SIR WILLIAM B DALBY, M B CANTAB, F R C S ENG,

CONSULTING AURAL SURGEON LATE AURAL SURGEON AND LECTURER ON AURAL SURGERY TO ST *GEORGE'S HOSPITAL.*

GENTLEMEN,—I beg to offer you my sincere thanks for having done me the honour to appoint me the first President of the Otological Society of Great Britain, and I venture to predict that this society has a great future before it Seeing that it comprises amongst its members all the aural surgeons attached to the metropolitan hospitals and very nearly all of the provincial hospitals, as well as those of Scotland and Ireland, it cannot fail to succeed and to exercise a very important influence on the progress of British aural surgery, for it will represent the work of the aural surgeons and will record it

The objects of the society are as detailed in its rules 1 The exhibition and demonstration of patients, models, drawings, and specimens (microscopical or otherwise), illustrating the anatomy, physiology pathology, and therapeutics of the ear 2 The reading of papers and the discussion of questions in otology previously approved by the Council 3 The investigation by committees—(*a*) of matters of public importance relating to otology, and (*b*) of new methods of investigation or treatment of the diseases of the ear

If I were to allow myself to comment on the avowed objects of this society it would be to say that I am much inclined to agree with the general view which I think I have detected amongst the members and especially the subcommittee which drew up the rules that the time of the meetings should not be occupied quite so much in the reading of papers as in demonstrations and discussions of questions which deal with treatment I think this opinion perhaps owes its origin to an idea that papers sometimes tend to be too discursive or to go over ground that has already been explored and thus to repeat what has been said by others and is therefore within the knowledge of the members We are all aware that the very best work in medicine and surgery has been through the medium of papers at various societies, but there are papers and papers, and I only mention the view which I think is generally shared, as I conceive it is my duty to give expression to the wishes and ideas of members of the society

The essential difference between this society and one composed of general surgeons is that whatever is brought forward is certain to be of great interest to every individual member who attends our meetings, for the subject is sure to be one upon which every member is working, and it has been felt that to bring before a society composed of physicians and surgeons a paper on a subject essentially one of aural surgery is to obtain for it very little attention and imperfect discussion It is in this that the great utility of our society will, we hope consist

Another point is that when cases are brought forward it is not only rare cases which perhaps few of us have seen before that will be welcome, but more ordinary ones in which if we have not seen the exact counterpart we have seen something so like that the very comparison is sure to throw some new light on the disease, for it is by incessant mental comparison that knowledge slowly but surely becomes more complete More light, more knowledge is what we all seek so long as we practise our art

I think what would be chiefly noticeable to a lay visitor if he were admitted into this assemblage of aural surgeons would be the comparative youth (with a few exceptions) of the members And the reason is not far to seek It is only of recent years that the progress of aural surgery has reached such a point as to attract young surgeons of good abilities and prospects to devote their lives to its practice I am not going to weary you with an account of this progress, for its remarkable history is within the memory of the older members, but to myself, looking back 25 years when I was beginning to work at our specialty, the contrast is very striking Three or four London hospitals only had aural surgeons on their staffs, at other hospitals the ear cases were distributed amongst the surgeons or perfunctorily attended to by an assistant surgeon Comparatively few patients attended, for the public had not learned to apply for aural surgery except at one well known institution The bulk of patients went for treatment to those who professed to treat and confined themselves to professing (for there was nothing beyond)

The changes which have taken place in our knowledge of diseases of the ear and in their treatment are not the only ways in which the practice of aural surgery has been affected For more than 20 years past there have gradually been established out patient departments and aural clinics at every one of our general hospitals, and in most provincial towns of any size there have arisen special hospitals for diseases of the throat and ear No earnest student considers that he has properly qualified himself till he has attended for some time in the aural department, and he gains there a very considerable knowledge of ear disease and its treatment, so that when he commences practice he considers himself, and often rightly so competent to treat ordinary cases which some years ago he would have sent for advice to an aural surgeon Now when he seeks the help of a consultant it is only to obtain his assistance in the complete diagnosis of the case and its future treatment, which he himself, unless it is a case of a serious nature, carries out Inasmuch as treatment often involves manipulations in which the practised hand of the specialist might be more beneficial some will be found to say that patients would be more successfully treated if they had throughout been solely under the care of the specialist Now, in my opinion this is a very narrow view to take of the situation For one person who might possibly make a more rapid recovery in this way there are thousands who at this period throughout the length and breadth of the land are by timely and judicious treatment by their medical attendant who has acquired his knowledge in the out-patient department, at our hands saved from those conditions which follow inflammatory processes within the middle ear, if these processes are allowed to proceed unchecked even for a few days Never can the spread of knowledge in the long run be anything but good, and never let it be said that the specialist of to-day (how different from the specialist of 30 years ago!) regretted for a moment that any skill which he may have acquired had become the property of others by his teaching I have practised my profession long enough to know that by the light which we have turned upon diseases of the ear at our clinics we have burned away, we have melted away, the areas of quackery which some years ago imposed upon the public to their loss and detriment to a degree unknown by the present generation

I hope I may be excused for saying a few words upon a subject which is at this moment agitating the minds of some general surgeons and all aural surgeons It is the operations which have for their object the protection of patients who are the subject of a disorder which renders them liable at any time to septicæmic poisoning and a rapid death I refer to those who are suffering from suppuration within the middle ear How attention is fixed upon this subject may be estimated by a glance at current otological literature which is full of it to the almost complete exclusion of any other The last volume of the Transactions of the American Otological Society is almost entirely filled with papers and discussions on this matter and a most important paper on a new method of operation was read by Mr C A Ballance only a few days ago before the Royal Medical and Chirurgical Society On this intensely interesting question we are going through a crisis—a revolution in surgery Let us remember that in all revolutions however righteous some mistakes must be made, for the man who makes no mistakes achieves nothing In all revolutions it is not without profit to look back for a moment to their origin There was a time not so many years ago when it was a recognised rule in surgery, and taught at every hospital to students, that the mastoid antrum should not be opened unless there was some redness, pain, œdema, or tenderness on pressure, or all of these symptoms—in short, the usual conditions of what was termed abscess At this period the mortality from cerebral abscess and meningitis was terrible, and surgical recognition was confined to the records of post-mortem examination. I shall not easily forget seeing in the year 1878 a patient with a recent perforation in the membrane and a profuse discharge, with a high temperature, who had had three severe rigors within 24 hours, with no symptoms of mastoid abscess, but in whom I made a wretchedly small opening into the antrum, letting out pus, and who made a rapid recovery. In the face of the methods of to-day I feel ashamed of the small opening Now, in regard to the operations for cerebral and cerebellar abscess which between that date and the present have come into practice we must confess that they were initiated and performed by general surgeons such as Mr. A. E. Barker, Mr. Victor Horsley, Mr. Ballance, Dr. W. Macewen, and others. I feel it as right and just to say this as I do to say that the mastoid operations were initiated by aural surgeons—so on this great question the general and aural surgeons meet on common ground.

I believe that I speak for both divisions when I say that during the period which is to be expended in the perfection of these operations, there will be no feeling of jealousy as to the encroachment of one into the domain of the other—there will be some aural surgeons who will gladly avail themselves of the skill of the general surgeon, as, indeed, has been largely done in the case of such men as I have mentioned, and they, on the other hand, will be equally glad to obtain the help and opinions of aural surgeons whose great experience in the local condition and history of these cases will carry great weight in the selection of cases, suitable or unsuitable, for operation At any rate, I believe I know that the one idea which will swamp all other considerations will be the security of life to each patient. You will forgive me if I am in any way presumptuous in speaking so plainly of a matter which is at the present time uppermost in our thoughts, but I feel confident that it will meet your wishes that I should refer to this part of our work which holds such a prominent position just now in British and foreign surgery.

A Clinical Lecture

ON

MENTAL DISSOLUTION.

Delivered at the Medical Graduates' College and Polyclinic on Jan 31st, 1900,

BY G. H. SAVAGE, M.D., F.R.C.P. LOND.,

PHYSICIAN FOR AND LECTURER ON MENTAL DISEASE, GUY'S HOSPITAL; LATE SENIOR PHYSICIAN AND SUPERINTENDENT, BETHLEM ROYAL HOSPITAL.

GENTLEMEN,—I recognise the responsibility of my position in addressing you who are anxious-minded searchers after medical truth. It is not as if I had to sketch an outline suited for the ordinary medical student and yet time will only allow me to indicate the lines of my subject. The most powerful idea of the generation is evolution and with it a great deal has been said about dissolution and the process has been considered as if it were but the reversal of evolution. This is only very partially true for there are many things seen in dissolution to which evolution gives no clue. Much may, however, be learnt by the study of dissolution as to growth and development, and my endeavour will be to point out some of this in relationship to mental dissolution. I shall at once proceed to my subject in detail and I think it will be best to introduce typical cases into the body of the lecture rather than to begin with examples.

Dissolution is separation into parts or constituent elements, reduction of any body or mass to elements or atoms, destruction of existing conditions, disintegration, decomposition. Hughlings Jackson has said: "I have often urged that for the scientific study of maladies of the nervous system we should investigate them as dissolutions (reversals of evolution) of this or that portion of the nervous system." It is rather with the idea of following these indications that I have selected dissolution in relation to mental disease for my subject to-day. In looking at the various definitions of the word "dissolution" I think I prefer separation into constituent parts or destruction of existing conditions. It is hardly necessary to point out that every compound may resolve itself into simpler elements. The very power of growth means the power of passing from the more into the less definite, passing from the stable into the unstable, from the condition of reacting to few stimuli to that of being able to react to many and varying excitants. In dissolution we get a reverse process—the passage to simpler states. Dissolution may serve the geologist in his search for the elements of the rock, "weathering" or weather dissolution making clear what was hidden before; in the same way the breaking up of the complicated facial bones clears up their origin and relationships, and similarly we shall learn much from watching the forms assumed or disclosed by the disintegrating mind. It must at once be said, that dissolution when properly studied must include temporary dissolution as well as that which is the result of normal wear and tear. We see parallelism in the temporary and the organic dissolutions. Thus a man suffering from drink, which for the time reduces his moral and mental level, has the same symptoms as the general paralytic who has progressive brain decay, and both resemble in some ways the decay due to old age. I say they resemble one another, but there are very marked differences. In studying dissolutions one has to remember that each structure varies in its stability and also in its power of resistance; the degeneration will depend in its character, too, on the causes of destruction. To put it concisely, there are some, I fear many, minds built on the jerry-builder's lines. They look all right, but they will not last long. Such degenerate persons come into the world only fit for very light work and they fail before they have reached any power or position; it is thus that certain boys and girls reach adolescence but get no further, their dissolution is progressive, and they pass into what resembles the undeveloped state of the imbecile.

There is then the class of dissolution in undeveloped persons and the symptoms as might be expected differ from those present in older patients. I only have time to say that they pass from defective self-control to impulsive violence, sexual excess, and mental weakness of a very marked and permanent kind. Then there are the cases of alcoholic dissolution which may be transient but on the other hand which may be permanent. In these cases the lines indicated by the temporary defects are generally followed by the more marked decay. The patient who during his drinking bouts becomes violent and aggressive with loss of all control of language, when he begins to become really and permanently weak as the result of continued excesses is equally violent, aggressive, and regardless of the conventions of his social surroundings. There is no doubt that the perfectly acting machine works without noise and it is equally true the perfectly fitting man best fulfils his functions quietly. In quietness we possess ourselves. One of the earliest and most marked signs of dissolution is want of resting power. This shows itself in constant movement, in perpetual talking, and in perpetual changes in occupation. I have seen many elderly ladies who wear their relations and maids to shadows by their constant movements. One no sooner is downstairs than she gets up to go to her room, when there turns out her various drawers and then leaves all in a muddle only to go down once more to return to another room or to another chest of drawers. In these patients as a rule there is defective memory and they do not recollect what they have done immediately before. The restlessness has seemed to me to resemble an "itch," and it may be associated with some skin irritability, so that such patients scratch themselves in any part of their bodies indelicately. I saw an aged lady the other day who with senility thought nothing of lifting up her dress in public and scratching her thigh. In some of these cases there is something more, a local sexual-organ irritability leading to sexual faults of various kinds to which I refer elsewhere. The perpetual talking is the evidence of defective education or is a kind of relapse into a lower form of culture. Dickens's characters said all they thought. The most cultured certainly consider that words, like Nature, should half-reveal and half-conceal the soul within. The older person with dissolution of his faculties will say all he is thinking and often seem incapable of tiring. A perfect logorrhœa is met with. Restlessness and changing occupation is often met with, but this is also associated with another type of mental disorder, namely, doubt Some of the dissolving patients can never make up their minds as to what they ought to do while others are ever from sheer restlessness moving from occupation to occupation. One rare and distressing symptom is that of swearing, or saying aloud what one would rather conceal. I suppose all will admit that with temporary dissolution due to alcohol a man will say things and use words he would not when quite under self-control. I have seen a gentleman who when suffering from a mental dissolution, which fortunately for him did not go too far for recovery, used to swear like a trooper and used to be heartily ashamed of himself for his bad ways. Loss of temper—i.e., loss of higher control—is often associated with the saying and doing things alien to one's nature, so with the dissolution of age or disease this may occur.

With dissolution, from time to time one comes across patients in whom the decay is chiefly marked by sensory hallucinations. Such cases may give rise to trouble from legal or medico-legal points and I will relate two very interesting cases. I was called to the north of England to decide whether an old man who undoubtedly had hallucinations was in a state requiring his detention in an asylum. I found a well-preserved old man who had made a large fortune. He was an old bachelor who had lived near the seat of his wealth and surrounded by valuable pictures and a pleasant garden. It was said that in consequence of thinking there were burglars about and believing that he saw them he fired a revolver out of his bedroom window. He told me at once that he knew he saw things which others said did not exist, but still he believed they were real. He asked, for example, if I saw a stream running across the dining-room floor, and on my saying I did not he said he did, but that having doubts he had taken blotting-paper to see if it became wet; it did not, yet he felt there was an overflow from the cistern running over the floor. He took me to the window and asked if I saw the rabbits. He pointed out what he believed to be a family with the young ones running in and out of the laurel bushes. I said no such rabbits existed, and asked if he would shoot at them if he had a gun; at once he said "No," yet he fully felt they were there. This state of defect had lasted for several years, and it was decided by the Court of Chancery that though he was not fit to manage an estate worth over half a million yet that he did not require asylum treatment.

I saw a shrewd and successful gentleman who on my being introduced said he was glad to have a talk with a nerve doctor for he thought there was something wrong. Then he told his tale, which was that he was pestered by gangs of gipsies who appeared everywhere. He said that he had just come in from chasing them in his garden for wherever he looked out he saw them pulling up his shrubs. I said, "But the shrubs are not removed, how do you account for this?" He said, "Well, it is hard to tell but I still feel they do it, and when I wake in the morning I see the same gipsies using my tooth-brush and my hair-brushes; I jump up only to find they have disappeared." He admitted the absurdity of the whole thing, but yet he said he felt it was true and he must act upon his belief. What might have proved a serious loss followed the persistent hallucinations, for before I insisted on his withdrawing from all business he had on one Bank Holiday gone to his office to look through his private safe with its very valuable securities; before leaving he thought he saw his son in the adjoining office and told him to put the things away and to lock the safe. The son was a hallucination and it was only by accident that the son discovered the state of affairs before others arrived next day.

In some cases one sees an interesting intermediate state in these cases of progressive dissolution, the hallucinations only occurring during states of reduced vitality. I have seen such haunted by some hallucinations on waking in the early morning, and an illness like influenza may start the same morbid process.

Though not wishing to make too much of it, yet I feel that I should point out to you that a certain number of patients, most of whom later have had some serious nervous breakdown, such as apoplexy, have very well-marked hallucinations of smell. This is very interesting to me, for though I do not say that the disorder of the sense of smell is always associated with some sexual disorder, yet I have found that it is a very common experience to meet with hallucinations of smell in patients in whom there is some sexual trouble. We have, then, to remember that in many of these cases of nervous dissolution we get hallucinations of smell and also sexual perversions. I have met with several patients in whom the hallucinations of smell have given rise to social or even legal trouble in consequence of the accusations brought by the patient against sanitary and other authorities.

One of the most characteristic signs of mental dissolution is the loosening of the mental unity. The individual is no longer himself. He has slowly been built up to fit into certain definite positions and the higher his social position and his professional work the more highly specialised has he become; with early signs of dissolution he ceases to be nimble in his social and other relations; the lady offends her friends; the politician is no longer to be trusted by his party and the religious man begins to be lax in his observances. Though this may be the whole evidence of decay yet it is very common for the signs of decay to be more marked. Let me take examples. The wife of a public man, his right hand in all social work, began to lose grasp of things and caused confusion to her husband's interests by getting the wrong people to meet each other and by doing the wrong things socially. In another case a man who was the soul of honour, with dissolution began to forget his debts of honour. Then he borrowed money even from his servants and never paid it back. Another, who had been dressy and precise, became dirty and untidy, and I may say that self-neglect and a state of dirtiness are very commonly met with in this state of dissolution. I have known a man to lie in bed for weeks together without once getting up to wash. Honesty may suffer in the process of decay, but probably the symptom which causes most trouble is the neglect of morality. Men who have led the most pure and virtuous home lives not only neglect their wives but consort and become the prey of very coarse designing women. One patient of mine saw nothing peculiar in travelling openly with his mistress, while he wrote daily to his wife in affectionate terms and in his letters openly described what "we" were doing. Men of the most strict life when passing to mental weakness seem first of all to lose self-control, they also appear to lose all power of judging of how their conduct appears to others. A leading Dissenter when he began to fail in mind spent money lavishly on designing women and saw nothing either improper or unconventional in expecting his family to entertain, or at least to receive, women of doubtful antecedents. It therefore is to be remembered that persons in the earlier stages of mental dissolution often become changed in every way, so that they pass from the moral to the immoral, from the quiet, peace-loving man to the boisterous roysterer. Sexual desire is increased or uncontrolled, and it is not very uncommon for me to be consulted about mentally failing persons who have done some indecent or indelicate or immoral act. Old men exposing their persons to children or to women, old men who take liberties with small children, and those who even exhibit signs of sexual perversions—I have had several such cases in whom the evidence of misconduct was clear and yet it was hard to find any other sign of mental failure, and it is in these cases that the jury and judge may most cruelly punish one who is irresponsible.

In general, memory is looked upon as the gauge of dissolution but I have to qualify this a good deal, for though in senility there is what I might almost call a normal decay in registering power, yet similar defects can occur quite independent of any general process of mental decay, and in some cases of progressive loss of mental power the memory is retained. First then, there is frequently in mental dissolution gradual failure of memory for recent events and the memory seems to be slowly driven back as it were till only the events of early life are recalled. The old man forgets what he has done during the early part of the day, repeats the same question, and tells the same tales.

I have not time to trace the lines along which the decay spreads, extending as it does from the isolated independent memory to that which is more organised and associated. Here I would call attention to the fact that the memory of the long past may appear with unusual vividness so that there is, or appears to be, an increase in exactness in memory of the long past. I remember an old officer who astonished me by going into the minutest details in reference to his regiment and its officers—details of the most trivial nature. At first I thought that this was but the old man's power of romancing, but on investigating some few of the statements I found that they were true. I have on similar occasions been able to show the probability of a clearing up of memory by denudation. This leads me to another important point. I have met with several patients who seemed to have gaps in their recent memories, so that they skipped from to-day back many years and confused the events of the past with those of the present. I have known the father forget the contrition of the prodigal son and wish to treat him as an enemy when he was by devotion attempting to atone for his youthful folly. In such cases serious legal complications might arise, because the father might act on his belief in the persistent wickedness of his son. Though such defects are common in mental dissolution, yet, as I have said, you may have progressive mental decay with little evidence of this. Thus in general paralysis of the insane the memory remains much longer active and good than would have been expected when you have to consider that there is a progressive decay of the highest nerve tissues. Again, great, almost absolute, defect of recent memory may be almost the only symptom of mental weakness. Such cases are met with most commonly in alcoholics. One patient of mine had no memory from moment to moment so that he could be got to repeat the same thing a dozen times in an hour without knowing that he had done the act before. This gentleman was fully able to reason on the past and though his memory became slightly more weak in sub-recent as well as recent affairs, yet he was in no way an example of a person passing through true mental dissolution. He was not progressively degenerating but only part of his nervous system seemed to be affected so that he could keep no recent sensory impression of any kind, and this leads up to the interesting subject of particular forms of memory and the special defects which may occur in them with age. Doubtless in dissolution, as I have said, the loss of power begins in the most independent and isolated impressions, but it may proceed to the more simple and organised; thus I have met with persons with mental dissolution who seemed to have no memory as to their appetite; they would eat and eat till they were sick and then begin again. There is not infrequently associated with mental dissolution an apparent increase of vigour, and I may here say that there is gain in some ways which is hard to explain. Many an old man sleeps more restfully than he has done for many years, his appetite and power of digestion are good, he has a return of sexual desire and on occasion sexual power as well.

I have already said that the rate of dissolution and the nature of the symptoms produced depend on the inherited and acquired nature of the whole nervous system. The restless, active-minded man might be expected to show the signs of wear and tear earlier than the more placid person, but this is not generally true. I see but few patients in whom dissolution is started by overwork, but I see a large number in whom the signs of decay are evident when the machine is slowing down. Men retire from very active pursuits to enjoy calm in old age and they do not get it. It is like the skater or the gymnast who while moving rapidly can do many things in which he would fail if he attempted while going slowly. So there seems as if there is a dissolution which I may compare to the rusting rather than the wearing out. Just as a healthy function should be unconscious, so soon as it becomes unhealthy it becomes first consciously, then painfully, evident. With early dissolution the unity, as we have seen, is broken and the harmony with it. Then come many uneasy feelings which receive various explanations. One patient will think that his body is seriously affected, that cancer has developed, that paralysis is imminent, or that he is suffering from some hidden but certainly fatal malady. With others various forms of melancholia occur among the signs of dissolution, the most common having the element of truth in them that they point to the decay which the patient says he feels. After all, the insanity rests in the interpretation of the morbid feeling.

Probably the most common interpretation of the morbid feeling of dissolutions is that which refers to poverty and the fear of the workhouse. This form of delusion is not confined to those who are suffering from mental dissolution, but it is more common among these than among others; it occurs chiefly in men or in women who have either had to earn their own living or else have had to manage their own business affairs. Every week I see some such case as the following. A healthy, active-minded man of very sensitive nature who has always had his hands full of work reaches the age of 70 years; he is still engaged in business, but he feels that he is not so [illegible] as he was and he is recommended to take rest and a holiday. This he does, but instead of being able to rest he cannot throw off the idea that something will happen to his affairs while he is away. He sleeps badly, he gets thin and worried, he can neither apply his mind to reading nor sight-seeing, his digestion suffers, and it is decided that he should return home. When he gets there he is more content for a short time, then the worries begin again; nothing assures him of his solvency, everything done in his absence involves him in disaster. He cannot sleep or rest and he becomes more and more the victim of his dreads. He is certain his bank is failing, that his clerks have robbed him, that he will soon be taken to prison as a fraudulent debtor, that all his professions of religion and philanthropy have been mockeries, and that the sooner he is dead the better. Such persons are very suicidal. Nothing will persuade the patients that the balance at the bank is all right or that the business affairs are in order; they say the proof you have brought them was right at the time but now some fresh thing has arisen which you do not understand and so reason is worthless and evidence of no avail. The weight of years and the interpretation of their gravity vary as I have said and this symptom is one of the most trying. It may lead to a melancholic ruin, the result of melancholic dissolution. There are many old wrecks who pass from active acute misery into the more chronic but hopeless form of the disorder and so live weaker in mind and suffering less acutely, but break up on rocks of melancholic delusions.

I have several times pointed out that the dissolution varies in form according to the original constitution and here I may say there are certain families in which the members being nearly all long-lived yet always end with prolonged depression. I have seen several such families. In one the members go on in useful public work till they are between 70 and 80 years of age when the first signs of physical decay occur; in one with gouty troubles, in another with neuralgias or respiratory troubles. Then comes the darker shadow of melancholia which may be thrown off once, or more frequently but sooner or later claims its victim. Under loss of higher control one has to consider the loss of control of the emotions. I suppose all of us who have passed 50 recognise that while we cannot leap and run as we did, and while we forget names and slight details that we also are more easily moved to express our emotions, at least some of them; a tale which we could have read aloud with expression and feeling enough to bring tears to the eyes of others did not affect us but now we struggle and stumble through the pathetic part with difficulty. At the theatre scenes affect us more readily than they did and yet we must recognise that the feeling is not increased, it is only the expression. That this is true must be known to all of us. The old man who loses his nearest relations does not suffer in the way a middle-aged man does and I have found but little difficulty in telling the worst news to very old people. With age then there is the loss of control not the increase of feeling; and this is parallel to what has been pointed out about other emotions, that the elder person may be sexually-minded but he may be impotent at the same time. In fact, Rabelaisian wit is suited to the older rather than to the younger men. Another exhibition of loss of control is seen in the violent passions which arise from small causes in many old persons. These storms are like the storm of passion in childhood which can be allayed rather by distraction than anything else. The passionate child must be interested in something out of the cause of trouble, and so with the old person we have to reckon with the facility of their emotions and to divert the stream.

In mental dissolution, then, we see various symptoms depending on defect of power and, as Hughlings Jackson has so often pointed out, with loss of power there is always a letting free of mechanisms which have been under control of the higher parts. So that with loss of power there is always a tendency to over-action on the one hand and defective action on the other. Dissolution may be regular in its progress or it may be irregular in its rate and also in the parts chiefly affected so that we cannot use any one faculty such as memory as a gauge of the depth of the dissolution. The effects of the dissolution will vary with the age of the individual and with his hereditary disposition. I have pointed out that, whereas certain persons seem built to last for very long periods before they break down along their nervous lines, others come into the world predisposed to break down with the first serious strain thrown upon them, and this is commonly of sexual origin. Though the very word dissolution seems to imply a hopeless condition, I would wish to impress on you the fact that though most people who live long enough show signs of failure, yet many even of those with marked defects due to dissolution by fresh methods of accommodation manage to carry on the life's battle to the end.

Remarks
ON
FETISHISM IN SURGERY.

By E. STANMORE BISHOP, F.R.C.S. Eng.,
HONORARY SURGEON, ANCOATS HOSPITAL, MANCHESTER.

IF I were asked to define what is meant by this term, I should, I believe, best express it by "a tendency to mistake the relative value of the various objects sought to be obtained or the various facts which go to bring about the result desired"—an error in mental perspective, in short. And such an error may either be committed by elevating a factor of relatively little importance to an unduly high level or by unconsciously depreciating or ignoring one of primary rank. The same attitude of mind is usually responsible for both. Of course, the word, as ordinarily employed, denotes the elevation of a totally unimportant and unworthy thing to a position of honour, admiration, and even worship; but amongst educated and scientific men fetishism to this extent is absurdly impossible. Such finer shades of it as I have indicated, however, are not only possible but occur with some frequency.

Every teacher of practical surgery must have encountered the student who has a profound respect for some particular author. Any attempt to demonstrate to such a student a proceeding which has not been described in so many words by his dominating genius is rejected because Erichsen, Heath, or Jacobson, whoever it may be, has not included it in his work. "Erichsen doesn't say so," is to him a sufficient answer. No power on earth can make such a man work his own brain. He accepts and registers as final the teaching of the particular writer whose text-book is accepted at the medical school of which he is a member, and no argument has any effect on him. His fetish is the written word of the teacher whom he was very properly taught to respect and believe in during his studentship.

Not very far distant from this condition of mind is that of the man who devotes himself almost fanatically to the writings of a particular nation. Not long since it was the fashion always to quote German authors. The man who had at his tongue's end and could always quote glibly Martin of Berlin, Duhrssen, Doderlein, Zweifel, Virchow, Koch, &c., with the magic references of *Berliner Klinische Wochenschrift*, *Sammlung Klinischer Vortrage*, *Centralblatt fur Chirurgie*, &c., was always certain of an awed, respectful hearing from this class of mind, who accepted almost blindly any dictum which emanated from Germany. The thing must be final, for was it not written in somebody's *Archiv?* His fetish also was plain.

Little different is the case of the man who prides himself on being "up to date." Is any method of surgical procedure praised or advocated? That is not the latest, and *therefore* not the best. Some man in Japan or in some unheard-of village in Russia has "brought out" a later plan. What is the date of the former? 1856. Dear! dear! perfectly obsolete, of course. So and so of Piatigorsk wrote a long article only last week in which the new method is described and above all things we must be "up to date" and swear by the latter, until in its turn it is displaced by another and still later method.

Now it will be noted that in all these cases there is an element which deserves respect, which is absolutely good in itself, and which only becomes wrong and misleading because it is dislocated, so to speak, from its proper place, and elevated to an undue prominence in the mind. Respect for the dicta of a teacher of the professional and mental rank of the names mentioned is most praiseworthy and to be encouraged. Respect for the painstaking, thorough, and usually complete work of the Germans has been well earned by them and should be ungrudgingly given. A desire to be acquainted with all that has appeared on our own special subject and not to be left behind and to become fossilised is absolutely necessary for all of us who desire to excel in our work. Accepted in due relationship to other and more important points, these are no hindrances, they are great helps. Elevated unduly in importance they become fetishes.

But fetishism is possible in minds otherwise constituted than those already considered. The modern surgeon is specially liable, it would seem, to fetishism in two directions, and the first is in that of undue importance attached to certain details in technique. No one who passed through it can have forgotten the controversy that raged between surgeons who used antiseptics and the "full Listerian method," as it was termed, and those who did not: the airs of impeccability that the first class—I was one of them—put on, and the sneers of the gentlemen who, in the elegant words of one writer in an American journal, "never bothered themselves about bacteria or bugs of any kind." Did the former lose a patient? the death was treated as of comparatively no importance—except as spoiling statistics—so long as the primary requisites had been complied with and the operation had been carried out under "complete antiseptic precautions." Some surgeons went even further, and not content with elevating the whole principle, almost worshipped some detail of it. A striking instance of this might be seen in the spray producer—that magnificent and imposing structure in brass, glass, and nickel-plate, which at one time was such a prominent feature in our operating theatres. Was the "spray" used? was the one essential question. If so, all was done that human ingenuity or skill could suggest, and if the patient was so wrong-headed as to die after that, well, it was his own fault, and no human power could have saved him. Now that the spray is relegated to the shelf does not the same tendency remain? and are we not tempted unduly to consider the importance of corrosive sublimate, hot air, steam under pressure, mercuric iodide, iodoform gauze, and a hundred other things according to the school in which we happen to have been taught, making these things principals, as it were, instead of looking upon them as simply means towards the one true end of all our work—the restoration to health of our patients? Some such feeling as this probably explains the opposition to Listerism of the late Sir William Savory and Mr. Lawson Tait, not to mention certain living writers.

The second direction is one of late date, but it bids fair unless checked to blossom into a fetish of great dimensions. In the old days, before our time, rapidity in operating was a point of first-class importance. When a patient was acutely conscious of every step in any operation he was the successful surgeon who could perform his work with lightning-like celerity. Every second of the awful bodily and mental anguish which could be spared to the unhappy victim was immense gain to his chances of life. But it must be remembered that operations in those days were almost limited to amputations. Take down any work, Chelius or Ambroise Paré, for instance, and turn up abdominal, gynæcological, or cranial surgery. The two former will be found to be almost non-existent, as we know them to-day, and the latter reduced to trephining, an operation usually performed under nature's own merciful oblivion. Every step of an amputation was known and had been practised many times beforehand. There was no careful separation of adhesions as in modern pelvic surgery, which process has frequently to be done before the surgeon can even be sure what it is he has to deal with or can decide what particular operative procedure has to be carried out; the position, size, and condition of all vessels were matters which had become commonplaces; there was scarcely a possibility of the surgeon being for one moment in doubt. How different in every way from the removal of an old pyosalpinx, buried in adhesions, with the imminent danger of rupture of the sac itself during the process, or the possible division of a ureter, or the perforation of an adherent loop of intestine. Once anæsthesia was introduced with its splendid elimination of mental and physical suffering, procedures never before possible came within the range of practicability, and the race with time became no longer an absolute necessity. It sank to the level of a factor of the third grade, and security with perfection in final results rose, as they ought to do, to the level of the second—the main end being now, as always, the recovery of the patient. But quite lately, as I have said, a most determined effort from a quarter which commands respect has been made to raise speed again to the level it originally occupied. Once more the skill of the surgeon, and, indeed, his reputation, is to be measured by the chronometer, and with the aid of the latest scientific—and popular—invention, the kinematograph, the powers of various men are to be judged of by the rapidity of their work. Not only so, but these records are to be handed down to posterity, and the operator is to be made to feel that he is not merely pitted against his contemporaries, but against all the surgeons of the future in this and all other countries. May it not follow as a matter of course that we shall vie with one another as to the rate at which we can open the abdomen, tear out the tumour, and sew all up again before the accusing film can have run half its course? Unfortunately the kinematograph will not record the after-condition of the patient, or the deaths which will inevitably follow from secondary or consecutive hæmorrhage, sepsis, or the miseries due to new adhesions, fæcal fistula, and the like. Rapidity in operative work is to be made a fetish, to which we shall all, for a time at least, have to bow [illegible] All, I say, but that is not so. Level-headed surgeons—and they are the majority—will, I am certain, refuse. Rapidity, like all other things, which carry with them this possibility of fetishism, is a good thing—a thing to be aimed at in its due proportion. Its opposite—dawdling or fumbling—is most strongly to be avoided, to be reprobated. But rapidity is good only when used in its true and fitting relation to other things. Always the main end to be kept in view is the sound and perfect restoration to health of the patient; and we must get that, or as near to that as possible, by the use of all these means in their due relation to one another.

The risks of undue rapidity—of racing—are many. Consecutive hæmorrhage is one of the most likely to occur. I watched carefully the reproduction of a hysterectomy by kinematograph at Edinburgh, and one of the things which struck me most forcibly was the extraordinary behaviour of the vessels in the abdominal wall. One stroke of the operator's knife and the abdominal cavity was open, one wipe down by the assistant with a piece of lint and all bleeding from the cut edges ceased. To go no further, what became of those vessels? Not a single pressure forceps was placed, not a vessel was ligatured, but there was no further bleeding—from those parts at least. I appeal to any surgeon who has ever done abdominal section if this is credible? If all parts are to be treated in the same way deaths from peritonitis afterwards are certain to be many. Clark and Waterhouse have shown that the peritoneum can deal with bacteria to a great extent if it is clean, but if any appreciable clots of blood are left behind or find later entrance peritonitis is promptly set up by the septic changes induced in such clots, where bacteria find a fitting breeding ground and immunity from rapid absorption and phagocytosis. Vessels treated in this lightning fashion will certainly bleed afresh when the force of the circulation recovers itself after the patient has returned to bed, when all is closed up and the mischief can progress unseen until it is too late to remedy. Will the kinematograph be re-introduced into the sick room and record for us the gasping, restless tossing of the exsanguine victim who is bleeding to death into her own abdominal cavity; or the hurried, anxious—often, alas! useless—groping of the surgeon with imperfect aid and light for the vessel now retracted into the subperitoneal tissues, or bidden under constantly increasing clot—that vessel which might so easily have been safely and finally secured in the morning had not the surgeon been racing against time in his devotion to the latest fetish of all—rapidity.

No protest can, I conceive, be too forcible against this new development of our art. Quick, nervous, prompt work is most desirable, but as all good things are liable to abuse, and such abuse is detestable in proportion to the very excellence of the thing abused, so racing in operative work is certain to entail results which will be as deplorable as those produced by careful rapidity are admirable. In surgery, as in everything else, a due perception of the proper perspective of things is absolutely necessary to produce perfect work.

Manchester.

TIVERTON INFIRMARY AND DISPENSARY.—The annual meeting of this institution was held recently under the presidency of Sir John Heathcote-Amory. The report showed that 1293 patients had been treated. The Victoria ened in August last by Lady Northcote, were now

EIGHTY SUCCESSIVE C
OPERATION.

BY PERCY JAKINS, M.D. DURH.,

SURGEON TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL

THE following consecutive series of 80 cases in which I have performed the radical mastoid operation (Stacke's) in cases of chronic suppurative otitis media serves to illustrate the symptoms demanding the performance of that operation and the beneficial results that may be expected. It should be premised that in all cases the procedure must be considered exploratory until the cavity of the antrum has been exposed, and by no method that I know can the medical man foretell with certitude what will be revealed. Broadly speaking, Stacke's operation consists in laying open the mastoid antrum and any diseased mastoid cells connected with it, opening the aditus leading from the antrum to the attic of the tympanum, cutting away all overhanging bone, removing the posterior wall of the osseous meatus, and in some cases removing the malleus and the incus. All morbid products, such as cholesteatoma, pus, granulations, and diseased bone, are then removed, the cavity is thoroughly cleansed and disinfected, the cartilaginous meatus slit, and the upper and lower flaps are cut away. This series of 80 cases could be increased to 124 by inclusion of 44 cases of Schwartze's operation, a procedure of similar import, except that the posterior osseous wall of the meatus is left intact. All these additional cases have resulted in recovery. It should also be added that concurrently my colleague, Dr. Dundas Grant, has had a similar series of cases of something like equal number. I think I may say that the success of both of us has been largely due to mutual conference and coöperation.

The indications for the performance of the operation are various. Together with persistence of purulent discharge one or other of the following symptoms was presented by these patients previously to operation: pain in the affected ear or corresponding side of the head, vertigo, nausea, vomiting, and general malaise; in some cases there were mental lassitude and a sullen demeanour. In most of them one or more of the following conditions was present: polypi or granulations in the tympanum, tenderness over the mastoid process, swelling of the meatus, bulging downwards of the posterior superior wall of the meatus and the adjacent part of Shrapnell's membrane, facial paralysis, caries of the ossicles or dead bone felt by the probe in the walls of the cavum tympani. The symptoms and physical conditions mentioned were rarely found singly but were mostly grouped in varying proportions. In every case the necessity for the operation was fully proved by the discovery of granulations, cholesteatoma, or necrosed bone, in the antrum or in the surrounding parts. In several of the cases it was necessary in the course of the operation to lay bare the dura mater in the middle fossa of the skull, to a greater or less extent, by the removal of a lamina of necrosed bone in the roof of the antrum. For the same reason the groove of the lateral sinus also was sometimes exposed in taking away a small piece of its bony wall. It was only occasionally that the mastoid cells became involved and required to be dealt with.

In recommending the operation the question of the effect upon the hearing power was naturally of but secondary consideration. It is, however, gratifying to report that audition was seldom rendered worse by the performance of the operation, while in some cases it was materially improved, probably owing to the removal of the accumulations of pus, granulations, and cholesteatomatous material which had filled the tympanum and so prevented the sound waves from reaching the labyrinth.

An examination of the appended table shows that out of the 80 patients operated on 45 were females and also that in 49 cases the left was the ear affected. The preponderance o the female sex among the cases cannot be explained, for it contrary to the statistics of the hospital with regard to a diseases of the ear, both acute and chronic. The preferen for the left ear is in accordance with what is generally no with regard to deafness, but especially in cases accompan with any degree of acuteness of inflammation. Len Browne[1] found that in 32 cases of othæmatoma the left

EIGHTY SUCCESSIVE CASES OF STACKE'S OPERATION: TABULAR STATEMENT.

No	Sex	Age.	Ear	Duration	Symptoms previously to operation	Date of operation	Remarks	Result
1	F	20	R	18 years	Recurrent polypi	Oct. 13th, 1896	Granulation tissue and cheesy matter in the antrum	Cured
2	F	6	L	—	Pain, nausea, and giddiness.	Oct 31st	Antrum contained granulation tissue	„
3	F.	27	L.	—	Pain and giddiness.	„ „	Granulation tissue and cheesy matter, dura mater exposed in the middle fossa	„
4	M	10	R.	—	Headache and mental dulness	Nov 20th	Fœtid pus in the antrum and granulation tissue	„
5	F.	25	R	8 years	Recurrent polypi	Feb 5th, 1897	Cholesteatoma in the antrum	„
6	F.	17	R	12 „	Recurrent polypi	March 5th	Granulation tissue in the antrum lateral sinus exposed	„
7	F	19	L.	15 „	Recurring polypi, pain, and giddiness.	„ 12th	Antrum was very large, full of granulation tissue	„
8	F.	13	L.	6 „	Swelling over the mastoid, pain	May 6th.	Mastoid cells, antrum and attic were full of granulation tissue and pus	„
9	F.	12	R.	4 „	Pain, giddiness, and recurring polypi	„ 13th.	Cholesteatoma in the antrum.	—
10	M	14	L.	5 „	Swelling over the mastoid, pain.	June 4th	Pus and granulation tissue in the mastoid cells and antrum, the incus was removed	Cured.
11	F	23	R	17 „	Pain, nausea, and giddiness	„ 8th	Mastoid cells and antrum contained pus and granulation tissue; the incus was removed	„
12	F	25	L.	9 „	Recurrent polypi and pain	„ 18th	Antrum was deep, granulation tissue	„
13	F.	29	L.	20 „	Pain and giddiness.	July 16th.	Antrum was very deep, granulation tissue	„
14	M	13	L.	—	Pain and recurring polypi.	„ 27th	Antrum was full of granulation tissue	„
15	M.	7	L.	14 days	Sinus over the mastoid leading into the antrum	August 3rd	Antrum was full of granulation tissue and cholesteatoma.	„
16	F	32	L.	14 years.	Facial paralysis, vomiting, and pain	Oct 21st	Pus and granulation tissue in antrum	„
17	F	17	R.	15 „	Nausea, pain, and giddiness	Nov 19th	Granulation tissue and cholesteatoma in antrum	„
18	F	25	R.	12 „	Pain, giddiness, and nausea	„ 30th	Pus and granulation tissue, dura mater of the middle fossa and lateral sinus were exposed	„
19	F	11	L.	8 months	Recurring polypi pain, and facial paralysis.	„ „	Mastoid cells were necrosed, antrum was full of granulation tissue, lateral sinus was exposed	Facial paralysis. Cured
20	M.	28	L.	20 years.	Recurring polypi, extreme pain, nausea, and giddiness	Dec 6th	Full of granulation tissue, lateral sinus covered with granulation tissue and thrombosed, left internal jugular filled with pus.	Died Jan. 6th, 1898
21	F	40	L.	38 „	Irritability, giddiness, nausea, shivers, and pain	Jan 18th, 1898	Antrum was very deep, cholesteatoma.	Cured.
22	M	13	L	12 „	Polypi, recurring facial paralysis	March 15th.	Full of granulation tissue, lateral sinus was exposed	Facial paralysis. Cured
23	F	26	L.	20 „	Nausea, pain and giddiness.	April 19th.	Granulation tissue and cholesteatoma, necrosed bone	Facial paralysis Well in nine months.
24	F	36	R	25 „	Pain, shivering vomiting and giddiness.	„ „	Granulation tissue	Facial paralysis Well in six months.
25	F	10	L.	6 weeks.	Mastoid swelling, fistulous opening leading into the antrum	„ 26th.	Granulation tissue, lateral sinus covered with granulation tissue	Cured.
26	M.	30	R.	25 years.	Recurrent polypi and repeated attacks of giddiness	„ „	Antrum deep, full of granulation tissue and cholesteatoma.	„
27	F	17	L.	1 year	Pain sickness, and polypi	May 24th	Antrum filled with granulation tissue	„
28	F	13	L.	2½ years.	Semi unconscious; head well retracted, bulging of the posterior superior meatal wall	June 15th.	Cerebellar abscess. (Published in the *Journal of Laryngology*, October, 1899)	„
29	F	1½	L.	12 months.	Polypi, mastoid swelling, and necrosed bone.	„ 18th	Disease of the whole temporal bone; antrum was full of granulation tissue and cholesteatoma	„
30	M	9	L	—	Mastoid swelling.	July 9th	Mastoid cells full of pus also antrum, and attic, with cholesteatoma.	„
31	F	15	L.	5 years	Pain, nausea, and giddiness	„ 19th	Mastoid cells and antrum full of granulation tissue, lateral sinus exposed	„
32	M	10	L.	—	Mastoid swelling, sinus in the bone leading to the antrum	„ 26th.	Carious bone in the mastoid cells, antrum enlarged, containing pus and cholesteatoma	„
33	M	23	L.	—	Stenosis of the meatus, pain and giddiness.	August 16th	Antrum filled with pus and granulation tissue.	„
34	F.	19	L.	3 years.	Facial paralysis	„ „	Antrum full of cholesteatoma, incus was removed	„
35	M	18	L.	—	Delirious, rigors, swelling over the mastoid, and great pain	„ 20th.	Pus over the mastoid and in the antrum, extradural abscess	Died August 22nd

EIGHTY SUCCESSIVE CASES OF STACKE'S OPERATION: TABULAR STATEMENT.

No.	Sex.	Age.	Ear.	Duration.	Symptoms previously to operation.	Date of operation.	Remarks.	Result.
36	M.	23	L.	3 weeks.	Mastoid swelling.	Sept. 3rd.	Full of granulation tissue filling the antrum, and also found on the lateral sinus.	Cured.
37	M.	8	L.	4 years.	Mastoid swelling, sinus in the bone leading to the antrum, and pain.	Oct. 5th.	Mastoid cells and antrum full of pus and granulation tissue.	,,
33	F.	20	L.	16 ,,	Pain, vomiting, and giddiness.	Nov. 8th.	Antrum full of pus and cholesteatoma.	,,
39	F.	15	L.	2 ,,	Subject to epileptic fits; no cause.	,, 8th.	Small granulations and carious bone in the attic.	Cured. Fits not improved.
40	M.	8	L.	7 ,,	Polypi recurring, drowsiness, and pain.	,, 29th.	Antrum full of large granulation tissue, also attic.	Cured.
41	F.	6	L.	3 ,,	Fistulous opening in the mastoid leading to the antrum.	Dec. 12th.	Mastoid cells and antrum full of granulation tissue; granulations over the lateral sinus.	,,
42	M.	8	L	2 ,,	Mastoid swelling.	,, 17th.	Antrum full of granulation tissue and pus.	,,
43	M.	8	R.	7 ,,	Mastoid swelling; sinus leading to the antrum.	Jan. 2nd, 1899.	Pus and granulation tissue in the mastoid cells and antrum,	,,
44	F.	13	L.	2 ,,	Recurring polypi.	Jan. 31st.	Antrum full of cholesteatoma and lateral sinus exposed.	,,
45	M.	7	L.	3 ,,	Pain, nausea, and giddiness.	Feb. 2nd.	Antrum very deep; granulation tissue.	,,
46	F.	20	R.	17 ,,	Giddiness and pain.	,, 21st.	Antrum full of granulation tissue.	,,
47	M.	13	L	8 ,,	Mastoid swelling, pain, and nausea.	,, 25th.	Antrum opened, full of pus and granulation tissue.	—
						March 2nd.	Extradural abscess.	—
						,, 10th.	Lateral sinus thrombosis; internal jugular vein tied.	Died March 21st Empyema of the chest.
48	M.	19	R.	—	Mastoid swelling; fistulous opening leading to the antrum.	Feb. 28th, 1899.	Pus in the antrum and granulation tissue.	Cured.
49	M.	24	R.	—	Pain, giddiness, and nausea.	March 14th.	Antrum very deep; pus and granulation tissue.	,,
50	M.	19	R	12 years.	Recurring polypi, pain, and drowsiness.	April 11th.	Carious bone removed, antrum full of granulation tissue. Lateral sinus exposed.	,,
51	F.	22	R	10 ,,	Pain, giddiness, and nausea.	May 9th.	Dura mater of the middle fossa exposed; antrum full of granulation tissue.	—
52	M.	32	R.	10 ,,	Giddiness, pain, and nausea.	,, 16th.	Antrum contained cholesteatoma.	—
53	F.	14	R.	10 ,,	Pain and nausea.	,, 30th.	Fistulous opening into the antrum; lateral sinus completely exposed.	—
54	F.	25	L.	20 ,,	Had attacks of epileptic convulsions.	June 2nd.	Antrum contained granulation tissue.	Cured.
55	F.	33	R.	20 ,,	Depression of spirits, pain, giddiness, and nausea.	,, 6th.	Antrum full of cholesteatoma.	,,
56	M.	20	R	—	Mastoid swelling, pain, and giddiness	,, 11th.	Antrum full of pus and granulation tissue; extradural abscess.	,,
57	M.	29	L	—	Pain, nausea, and giddiness.	July 18th.	Antrum and attic full of granulation tissue and cholesteatoma.	—
58	M	28	L	20 years.	Pain and recurrent polypi.	,, 25th.	Antrum contained granulation tissue.

78	M.	5	L	—	Mastoid swelling and pain.	,, 28th.	Fistulous opening leading into the antrum containing granulation tissue.	,,
79	M.	26	R.	14 years.	Pain, nausea, and giddiness	,, ,,	Antrum was very deep and contained granulation tissue	,,
80	F.	24	L.	18 ,,	Pain, nausea, and giddiness.	Dec. 12th	Antrum contained granulation tissue; lateral sinus exposed	,,

For the notes of these cases I am indebted to my colleague, Mr. Chichele Nourse, who has more especially followed their progress.

was affected in 19 instances, in both ears in 11, and the right ear only in two cases. In those cases in which both were affected the left ear was first attacked. His explanation of the fact is the nearer position of the left common carotid to the heart and the more direct and less impeded arterial supply to the left than to the right side of the head, this observer noting, also, that arachnoid cysts so frequent in that form of mental disease in which othæmatomata may be expected are more commonly found on the left than on the right hemisphere of the brain The average age of the patients is between 20 and 21 years, the youngest subject being 14 months old. The average duration of the suppurative disease in those cases where it could be ascertained was 12½ years.

Turning now to the symptoms exhibited by patients before the operation, persistent suppuration of the middle-ear was present in all and pain was very commonly complained of. 39 of the patients were troubled with attacks of vertigo, in 19 there were recurrent polypi, and in 17 there was swelling over the mastoid process. Facial paralysis was present before the operation in five cases and mental disturbance was noted six times. In two cases of old standing suppuration (Cases 39 and 54) the operation was mainly undertaken in the hope of curing the epileptic fits to which the patient had recently become subject. Though the conditions discovered proved that the operation was abundantly justified the fits showed no improvement in Case 39, but a complete cure resulted in Case 54 The original disease was complicated by septic phlebitis of the lateral sinus and the internal jugular vein in two instances and by extradural abscess in three Cerebral abscess was found once and cerebellar abscess once. At the time of the operation dead bone was discovered and removed in seven cases. In 11 a fistulous opening led from the surface of the mastoid process to the antrum. The middle fossa of the skull was exposed six times during the operation and the groove of the lateral sinus was laid bare in some part of its course 14 times. The cerebral and cerebellar abscesses were successfully located and drained and in one fatal case the internal jugular vein was tied. In two cases facial paralysis appeared after the operation, but in both it disappeared again within nine months. Except in those patients—three in number—whose condition was almost beyond hope on admission the results of the operation were uniformly successful.

With regard to the results of this operation the mortality in my hands has been practically *nil*, for the only three deaths reported were brought into the hospital in a very advanced stage of pyæmic poisoning. In the successful cases the threatening symptoms quickly disappeared, the change from sullen stupidity to lively intelligence being very noteworthy. Occasionally a slight purulent discharge continues for some time; but owing to the freedom with which the adjacent cavities have been placed in communication with the now very wide meatus no accumulations can possibly occur, and the whole tympanum, antrum, and attic gradually become soundly healed and can be inspected at any time by means of a speculum. In conclusion, my experience leads me to the opinion that it is safer to operate at an early period of suppurative disease, should there exist any of the enumerated indications for it, rather that wait until the processes have had time to produce signs of a more threatening character, and possibly to infect some of the intra-cranial contents.

Harley street, W.

CONSANGUINEOUS MARRIAGE AND DEAF-MUTISM.

By ALFRED H. HUTH,

AUTHOR OF "THE MARRIAGE OF NEAR KIN"

THE question of the intermarriage of the deaf and its consequences has excited attention almost ever since deaf-mutism itself has been studied, and very various opinions have been expressed upon the subject. On the one side is the remarkable fact that frequently none of the children of deaf parents are deaf, while on the other side we have the indisputable fact that deafness is as strongly inherited as any other disease of the nervous system. In short, this is another example of the now generally accepted axiom that inheritance equals the sum of the ancestry divided by the number of the ancestors, and since there is, at present at least, no deaf race of human beings so the inheritance of deafness must be proportionately uncertain. In the absence of reliable statistics it is difficult to ascertain how far this inheritance is likely to be intensified by the intermarriage of the deaf. Such marriages are not very common in Europe. In the United States, however, where for the last half century a great deal of attention has been paid to the education of the deaf and where consequently they have been more intimately brought together, so much intermarriage has gone on as to excite the alarm of many observers. In 1884 Dr. Graham Bell, the well-known creator of the Volta Bureau of Washington, published his "Memoir upon the Formation of a Deaf Variety of the Human Race," and now Dr. Fay comes forward with an elaborate inquiry into the result of "Marriages of the Deaf in America." By means of circulars and other investigations Dr. Fay has [illegible] total of 3078 marriages, [illegible] drawn from them, and which he has reason to believe represent all the marriages of this kind which have taken place in the continent of North America within a given period. These results he has tabulated and analysed and, as far as the figures allow, he shows that the average of sterility is not greater among such marriages than among the general population; that marriages where both the parties are deaf do not intensify the chance of deafness being inherited by the children, but double it; that since deafness is due to a variety of causes, parents are less likely to transmit their defects whose deafness is due to different causes; and that congenitally deaf parents are far more likely to transmit their deafness than are those who have become deaf since their birth. As to the vexed question as to the effect of consanguineous marriages, he comes to the conclusion that they have no effect beyond the ordinary laws of inheritance—that is, that the probability of inheritance by the children of the defects of their parents is not intensified by the relationship, but is proportionate to the amount of deafness in the ancestry.

Dr. Fay's inquiries only apply to marriages of the deaf, and these, in so far as they were sufficiently reported, numbered, as I have said above, 3078. From these we must, however, deduct 434 marriages which were barren, or 14·1 per cent., leaving 2644 productive marriages, which produced 6782 children. Of these 290 children died before it could be ascertained whether they were deaf or not, and 588 were deaf. As the result, therefore, of 2644 marriages there were 588 children who were deaf and 5904 children who could hear, thus giving 9 per cent. of deaf children and 2 45 children for each productive marriage. Among the 3078 cases of marriage of the deaf Dr. Fay notes 31 cases of consanguineous marriage in various degrees, but he nowhere states how many of these were barren. I can only trace the following from his material :—

Consanguineous Marriages producing Deaf Offspring.

Relationship.	Number of marriages.	Number of children.	Number deaf.
Aunt and nephew	1	4	3
Second cousins	4	17	5
"Cousins"	12	31	9
Total	17	52	17

But in these there is no information regarding the offspring of two marriages of "cousins," one marriage was barren, and in one the number of children is not stated, but "all" were hearing children. Clearly, therefore, at least four marriages must be deducted from the 31 cases. The result is as follows :—

Result of Marriages of the Deaf which produced Offspring.

Relationship.	Number of marriages.	Number of children.	Number deaf.	Children per marriage.	Percentage of children deaf.
None ...	2617	6392	558	2 44	9·2
Consanguineous.	27	100	30	3·7	30·0

We must remember, however, that here only those consanguineous marriages of the deaf which produced at least one deaf-mute are compared with marriages of the deaf most of which produced no deaf offspring, and therefore the comparison is without value. In any case, even taking Dr. Fay's total number of 31 consanguineous cases, the number is far too small to draw any reliable conclusions from. I have, however, drawn from Dr. Fay's material 302 cases of consanguineous marriage which I have tabulated. They do not represent the liability of consanguineous marriage to produce deafness, but appear solely because they have produced deaf children, and therefore the only value of the table is to show that nearness or distance of relationship is without effect. Indeed, we find that the most distant relations produced 100 per cent., first cousins produced 42 per cent., while fourth cousins produced 75 per cent.

Results of Marriages between Relations which produced Deaf-mutes.

(From Fay's "Tabular Statement," including Non-congenital Cases.)

Relationship.	Number of marriages.	Children. Deaf.	Children. Hearing	Children per marriage.	Percentage of children deaf.
Nephew and aunt	1	3	1	4 0	75 0
First cousins	9	29	40	7·67	42·0
Second cousins	55	109	178	5·2	38 0
Third cousins	26	44	63	4·0	41·1
Fourth cousins	7	15	5*	3 1	75 0
"Cousins"	190†	387	675	5 6	36 5
"Related"	10	26	30‡	5·6	46·4
First cousin once removed	3	14	11	8·3	56 0
Second cousin once removed	1	4	—	4 0	100·0
Totals	302	631	1003	5 41	38·6

* "Several" hearing children are put down as three.

† Omitting four cases insufficiently reported and two with no deaf offspring.

‡ Five "unknown" are entered as hearing children.

Although, however, there is no evidence that consanguinity produces deafness, or, indeed, as I have shown in my "Marriage of Near Kin," any other disease, it is not advisable on the grounds of heredity for a deaf person to marry a relative when there is deafness or even a tendency thereto in the family. Dr. Fay found that nearly 21 per cent. of the children where at least one of the parents was deaf and both parents had deaf relatives were themselves deaf; under the same circumstances, but where only one of the parents had deaf relatives, only 6·4 per cent. of the children were themselves deaf; while where there were no deaf relatives only 1 2 of the children were themselves deaf.

Dr. Fay's statistics have a very considerable value for two reasons. First, that they are all derived from one nation and probably represent the whole of the deaf population of that nation over a considerable period; and, secondly, that they are not taken from asylums—that is, working back from the pupils to their parentage, but are an investigation of the results of the marriages of the deaf. Nearly all of the statistics on the subject which had appeared before were derived from an investigation of the relationship between the parents of the children in asylums. The difference between the two is radical. Where there is deafness in the family the proportion of deaf children per family is very much greater than the proportion of deaf children per family in the general population. Hence if an undue proportion of children derived from consanguineous marriages appears in asylums, it does not follow that consanguineous marriages on the whole, including those where there is no deafness to inherit, produce an undue proportion of deaf children. Moreover, the reports from the various asylums are founded on so small a number of cases and are so biased by the preconceived opinions of the reporters that they require very careful investigation and verification.

In the year 1889 the Royal Commission on the Blind, the Deaf, and the Dumb, &c., reported on the result of their inquiries. Among these was the effect of consanguineous marriage on the production of deafness. As to this they say, "We think from the evidence and statistics before us that consanguineous marriages should be strongly discouraged, especially where deafness has occurred in the family." The last part of this sentence is merely a reference to the ordinary laws of inheritance; but what evidence had they before them for recommending the discouragement of consanguineous marriage where there was no history of disease in the family? Mr L. van Ofen, one of the Commissioners, dissents entirely from this recommendation. "I have carefully examined the evidence of the various witnesses," he says, "on this point, and I find that as a rule they either rely upon general impression or upon the fact that they have known a certain number of deaf mutes whose parents were *first or second cousins, without having investigated whether* there were any other circumstances such as deafness in the ancestry or collateral relatives of such parents, and without knowing whether the proportionate number *of such cases—viz, marriages of blood relations having* deaf offspring—was larger than the proportionate number of such marriages to the general marriages of the district I do not deem it desirable or necessary to argue upon or refute the evidence of witnesses who base their evidence upon conjecture though much might be said against the conclusions they arrive at and in some instances their assertions could be entirely disproved As regards the returns made by the institutions I find that they are so imperfect that no satisfactory statistics can be made from them Until more correct records are kept and the statistics are more carefully compiled I think that no reliable deductions on this point can be drawn from them *Mr van Ofen's strictures are amply confirmed by* the published evidence Some of the witnesses did not hesitate to pronounce an unqualified opinion against consanguineous marriage without advancing or apparently *being able to advance, a particle of evidence in support* of their views Others did the same on perfectly ridiculous evidence Then there is the evidence of Dr R Elliott and Mr W H Warwick head master and secretary *respectively of the asylums for the deaf and dumb in the* Old Kent road and at Margate one of whom says that there were 8 per cent on 550 pupils "the offspring of relations", while the other says that 52 children of first and second *cousins have passed through the school since the year 1875* when statistics upon relationship of the parents first began to be collected, but he does not give the total number of children In the official return supplied by these two institutions there were then 343 *pupils out of whom 22*, or 6 4 per cent, were derived from 'cousin marriages' I cannot tell what weight the Commissioners attached to this evidence, but being myself quite unable to reconcile the various statements *I obtained through the courtesy of* Mr Warwick the following additional information from Dr Elliott "I cannot find the particular notes which I referred to in my evidence before the Commission I think however, *the 8 per cent I then mentioned referred to the 350 children* then (in 1886) in the institution to which number reference is twice made just before and that 550 is a typographical error I have before me a list I drew up from our register some years ago of children elected July 10th 1876 to (I think) August 1884 548 cases And he gives the following consanguineous cases out of this total —

Margate and Old Kent road Asylums

Relationship of parents	Number of pupils.	Percentage on 548.
First cousins	25	4 56
Second cousins ..	3	0 55
Cousins" ..	10	1 82
Grandparents first cousins	2	0 37
' Related	1	0 18
Total	41	7 48

He adds "I have not the particulars here whether they are or are not congenital cases of deafness' Even supposing however that all are congenital cases I cannot find in these figures any suggestion that consanguineous marriage is more productive of deaf mutism than any other marriages seeing that the proportion of consanguineous marriages to other marriages must be fully as great as if not greater than, the 7 5 per cent here shown

Another witness Dr E Symes Thompson, says "45 per cent of the applicants for admission to Ealing have been the children of first cousins In the official return to the Commissioners from the Ealing College the total number is given as 18 of which only one is said to be the offspring of cousins I therefore wrote to Dr Thompson and through his kindness obtained the following figures from the lady superintendent concerning the pupils who had passed through the college from 1878 to 1889 —

Ealing Training College

Relationship of parents	Number of families represented	Number of deaf in college.		Number of brothers and sisters not in college.		Total
		Congenital	Non congenital	Deaf	Hearing	
First cousins	3	—	—	—	—	—
Relationship not specified	5	—	—	—	—	—
Total consanguineous	8	7	1	10	5	23
No relationship	35	17	18	—	30	65
Total	43	24	19	10	35	88

It will be seen that these statistics labour under the disadvantage of being exceedingly small, and they unfortunately do not tell us the whole number of children born in each family or the number of those outside of the college who were congenitally deaf But taking the figures as they stand we have —

—	Relatives	Non-relative
Percentage of families affected	18·6	81 4
Average of children per family	2 89	1 85
Percentage of congenitally deaf in college	29 2	70 8
Percentage of all deaf in and outside college	34 0	66·0

Another witness is Mr Hillyer, the secretary of the British Asylum at Clapton who makes the statement that "we find most of the deaf mutes are the children of those who have married cousins But on turning to the reports of the asylum I find that they give no return on the question of consanguinity since the parents were either unwilling or unable to give *information In reply to my inquiries* Mr Hillyer wrote that his statement was based very much on the experience of their training master Mr D Murray The latter gentleman however, hardly goes so far in his evidence before the *Commissioners for he considers the* intermarriage of deaf mutes to be a far more potent cause nor in his reply to me does he confirm Mr Hillyer's opinion

Of the other witnesses who gave evidence, Mr J de Castro found that five out of 31 or 16 7 per cent, were the children of first cousins Mr W S Besant out of a total of 200 children found that two were the offspring of cousins and one the child of distant relatives or together 1 5 per cent Mr F Townend also supplied a table of statistics which I condense for my purpose as follows —

Inter marriages among the Deaf mutes of Birmingham

Description of marriage	Number of marriages	Total number of children	Average number of children per marriage	Number of children deaf
Both parents deaf mutes	16	54	3 37	3
One parent deaf mute ..	6	19 or 20	3 2	2
First cousin one deaf	1	4	4·0	0

Another witness of considerable experience, Mr A Welch, never found a single case in which there was consanguinity of the parents, although he found many cases of the marriage of two deaf mutes

In the official returns from 24 institutions in which some record had been kept as to the consanguinity, if any of the parents on a total number of 1918 deaf-mute pupils, congenital and non-congenital cases, there were :—

Relationship of the parents.	Deaf-mute offspring. No.	Deaf-mute offspring. Per cent.
First cousins	43	2·24
Second cousins	17	0·99
First and second cousins	11	0·57
"Cousins"	2	0·1
More distant relatives	26	1·35
Total of consanguineous	101	5·26
Total of non-consanguineous	1817	94·73
Total	1918	100·00

In six of these institutions, comprising 331 cases, there was no case at all of consanguineous origin, but they are all included in the above table.

From nine board schools comprising 198 pupils, from which the Commissioners obtained returns, there were six cases in which the parents were first cousins, or 3 per cent. The Commissioners further give an extract from the report for 1887 of the American Asylum of Hartford, Conn., in which there is a list of all the children admitted during the previous 10 years, together with references to their relatives, of which I have made the following summary :—

Relationship.	Number of families represented.	Congenital deaf-mutes.	Non congenital deaf-mutes.	Particulars not stated.	Total number of deaf-mutes.	Total number of hearing children.	Total number of children.
Uncle and niece	2	1	1	0	2	6	8
First cousins	8	7	3	6	16	32	48
Second cousins	3	3	1	1	5	12	17
Third cousins	4	2	2	0	4	6	10
"Cousins"	9	3	6	2	11	31	42
Grandparents cousins	2	2	0	0	2	3	5
Total consanguineous ..	23	18	13	9	40	90	130
No relationship ...	34	38	7	35	80	99	179
Totals	62	56	20	44	120	189	309

This summary forms a very extraordinary table indeed. Out of a total of 56 congenital deaf-mutes 18, or 32 14 per cent., were of consanguineous origin. Put as averages per family we have :—

Relationship.	Congenital deaf-mutes.	Non congenital deaf-mutes.	Particulars not stated.	Total average of deaf-mutes.	Total average of hearing children.	Average of children per marriage.
Uncle and niece .	0·5	0·5	0 0	1·0	3·0	4 0
First cousins ...	0 9	0 38	0 75	2 0	4·0	6 0
Second cousins ...	1·0	0·34	0 34	1 7	4 0	5 7
Third cousins ...	0 5	0 5	0·0	1 0	1·5	2 5
"Cousins"	0 34	0 69	0·23	1·2	3 4	4 7
Grandparents cousins	1·0	0 0	0 0	1·0	1 5	2 5
Total consanguineous	0 64	0 46	0 32	1 43	3·21	4 64
No relationship ...	1·12	0·2	1·0	2 35	2 9	5 27

From the above table it appears that the greatest number of congenital deaf-mutes per family will be produced where there is no relationship between the parents, the next greatest number where the grandparents are cousins or are second cousins, while a marriage between an uncle and a niece is less likely to produce many deaf-mutes than any other. In this school it also appears that the non-consanguineous marriages were more prolific than the consanguineous marriages, which is contrary to the most reliable evidence.

At the Illinois Institution, Jacksonville, Ill., out of a total of 1886 pupils from 1075 families, there were 113 belonging to 88 families who were derived from consanguineous marriages as follows :—

Derived from uncle and niece... ... 1 case, or 0·05 per cent.
" first cousins ... ... 76 " " 4·00 "
" second " ... ... 17 " " 0·9 "
" third " ... ... 9 " " 0·48 "
" fourth " ... ... 9 " " 0·48 "
" grandparents first cousins 1 " " 0·05 "

The consanguineous marriages come together to nearly 6 per cent. on the total number of cases; but the principal, Mr. P. G. Gillett, does not state how many of these were congenital. He merely says that of the whole number of 1886 pupils, 490 were congenital deaf-mutes, which is 25 9 per cent. The average number of deaf-mutes per consanguineous marriage is 1·25, and per non-consanguineous marriage, 1·8.

At the Georgia Institution, Cave Spring, Ga., there were returns on 258 cases, which I have tabulated as follows :—

Relationship.	Number of families represented.	Number of deaf children	Average per family.	Percentage on total of deaf-mutes.
First cousins	20	33	1·65	12 8
Second cousins	11	18	1·65	7·0
Third cousins	4	7	1·75	2·7
Fourth cousins	1	5	5·00	1·9
Half cousins (?)	1	1	1·00	0 38
More distant relatives .. .	3	5	1 7	1 9
Total related	40	69	1·72	26 7
No relationship	45	189	1 3	73 26
Total	85	258	1·4	—

Similarly I have tabulated the return from the New Jersey School, Chambersburg, near Trenton, N.J , as follows :—

Relationship.	Number of families represented.	Number of deaf children.	Average per family.	Percentage on total of deaf-mutes.
First cousins	1	2	2	1·5
Second cousins	1	2	2	1·5
Third cousins	1	1	1	0·8
Total consanguineous	3	5	1·7	3·7
No relationship	34	129	3·5	9·6
Total	37	134	3·6	—

These figures seem hardly to bear out the very decided conclusion of the Royal Commissioners, and fully justify the protest of Mr. van Ofen.

It is lamentable to see all this misdirected work and wasted energy and money, due simply to the refusal of the Government to insert a simple question into the census. It need not be repeated. The expense of the Royal Commission on Deaf-Mutes, &c , would have been saved, the work of countless medical men would be made useful, the public would have their doubts set at rest for ever. Since the year 1851 the Irish Census Commissioners have inquired into the number of deaf-mutes and their parentage, but never yet have they inquired into the relationship, if any, of married persons in that country. The consequence here again is a great waste of money and labour, with results that are no more reliable than those obtained by the Royal Commission, except in so far as they are on a larger scale. Even then they permit themselves to draw conclusions which on the evidence obtained are untenable, and present their statistics to the public in a form that is misleading. Only in the years 1871 and 1881 are the special relationships returned. I have disentangled them from the non-congenital or adventitious cases and from those where the patients were not both deaf and dumb, with the following result:—

Irish Census Reports.

Relationship.	1871. Number of marriages.	1871. Number of congenital deaf-mutes.	1871. Average per marriage.
First cousins	62	98	1·58
Second ,, ...	50	89	1·74
Third ,, ...	24	40	1·67
Fourth ,, ...	5	11	2·23
Fifth and sixth cousins ...	12	19	1·58
Total	153	257	1·68
Non-related	2852	3246	1·14
Total	3005	3503	1·17

Relationship.	1881. Number of marriages.	1881. Number of congenital deaf-mutes.	1881. Average per marriage.
First cousins	74	123	1·66
Second ,, ...	29	46	1·55
Third ,, ...	9	21	2·34
Fourth ,, ...	1	1	1·00
Total	113	191	1·69
Non-related	2474	2972	1·20
Total	2587	3163	1·22

An examination of the above table will show that these statistics, so much relied upon to prove that deaf-mutism is caused by consanguineous marriage, proves nothing of the sort. In 1871, fourth cousins produced a greater proportion of deaf-mutes than any nearer relationship, and first cousins less than any others. In 1881 third cousins produced a greater proportion than any other nearer relationship. Comparing the whole of the reports from 1851 to 1891, though the special relationships are not given, we have the following:—

From the Irish Census Reports.	1891.	1881.	1871.	1861.	1851.	Averages.
Total number of congenital deaf-mutes derived from consanguineous marriages	297	191	257	297	199	248·2
Total number of congenital deaf-mutes derived from non-consanguineous marriages ...	2273	2972	3246	3799	3686	3195·2
Average number of congenital deaf-mutes per consanguineous marriage	1·92	1·69	1·68	1·44	1·03	1·62
Average number of congenital deaf-mutes per non-consanguineous marriage	1·27	1·20	1·14	1·14	1·12	1·17
Percentage of congenital deaf-mutes derived from consanguineous marriages	11·56	6·04	7·34	7·25	5·13	7·45

I cannot vouch for the precise accuracy of these figures, as the language of the Census Commissioners is very loose. The figures for 1851 include the cases of persons who were not living in that year; and perhaps the others do also. At all events, as far as this table may be relied upon, we do not see any tendency in consanguinity to produce deaf-mutism in itself, as the Census Commissioners say we should. We do see a slight intensification of a family tendency to deaf-mutism in the half per family greater number of deaf-mutes from cousins up to the sixth degree; and even this difference must be accepted with caution, since in some instances, certainly, the Commissioners have included in their figures *all* the children born in *those* families where the parents were related, whether living or not at the time of the inquiry, while there is reason to believe that this has not been done in the case of the non-consanguineous marriages. Even if the figures could be absolutely relied upon, however, as I have already pointed out they would by no means prove that a greater proportion of deaf-mutes are born from consanguineous marriages, though they do indicate that where there is a family taint of deaf-mutism more deaf-mutes are likely to be born in families when there is double inheritance through the relationship of the parents than when this is not the case.

Looking at the percentage of 7·43 deaf-mutes derived from cousins up to the sixth degree it would seem that on the whole these marriages produce less than their due proportion, seeing that in all probability the marriages between cousins so widely related must be more than that percentage of the whole number of marriages in Ireland.

FURTHER OBSERVATIONS ON PERNICIOUS ANÆMIA (SEVEN CASES): A CHRONIC INFECTIVE DISEASE;

ITS RELATION TO INFECTION FROM THE MOUTH AND STOMACH; SUGGESTED SERUM TREATMENT.

BY WILLIAM HUNTER, M.D. EDIN., F.R.C.P. LOND.,
PHYSICIAN TO ELECTRICAL DEPARTMENT, JOINT LECTURER ON PRACTICAL MEDICINE, AND PATHOLOGIST, CHARING-CROSS HOSPITAL;
SENIOR ASSISTANT PHYSICIAN TO THE LONDON FEVER HOSPITAL.

(*Concluded from page 299.*)

VI.—EVIDENCES OF GASTRO-INTESTINAL INFECTION.

Frequency of gastro-intestinal symptoms.—The symptoms of gastro-intestinal disturbance include, I find, not only vomiting and diarrhœa but almost every variety and degree of disturbance—e.g., indigestion, anorexia alternating with ravenous appetite, nausea, sickness, pyrosis, salivation (rare), acidity, retching, vomiting, gastric pain, dilatation of the stomach with splashings, general discomfort over the stomach, looseness of the bowels, diarrhœa, and colicky pains. An analysis of a total of 273 recorded cases which in the light of the foregoing conclusions I have been interested to make shows that the frequency of such symptoms is even greater than supposed.

A Table showing the Frequency of Gastro-intestinal Symptoms in 273 Cases.

Author.	Number of cases.	Number in which gastro-intestinal symptoms are recorded.	Percentage.
Eichhorst (1878) ...	91	71	78
Lasche (1883)	11	9	81
Hale White (1890) ...	29	25	86
Byrom Bramwell (1899)	47	40	85
Hunter (cases from the literature of 1890-1896) ...	88	73	83
Hunter (1900) ...	7	6	85
Total	273	227	83

NOTE.—I have not included in this analysis the very full and complete record of cases (103 in number) given by Dr. Pye-Smith in his article in 1882, since this includes not only all the earlier cases recorded by Müller and Eichhorst, but also many of those from the records of Guy's Hospital subsequently analysed in Dr. Hale White's list of cases.

The most striking of these symptoms of gastro-intestinal irritation are vomiting and diarrhœa, and their prominence is best brought out by Dr. Hale White's analysis of 29 cases from the records of Guy's Hospital—viz., before admission: vomiting 12 (or 41 per cent.), diarrhœa 10 (34·5 per cent.); after admission: vomiting 16 (or 55 per cent.), diarrhœa 12 (or 41 per cent.). Dr. Cabot's analysis of 50 cases (33 of males and 17 of females)[1]: Nausea and vomiting in 31 cases (62 per cent.), diarrhœa in 12 cases (24 per cent.), constipation in 13 cases, and regular in 13 cases.

Gastric and intestinal lesions.—In the stomach the changes described in individual cases (and these constitute a very considerable proportion of those microscopically examined), I find on detailed analysis of the records of over 150 cases, include every stage of catarrh of the mucosa and its effects—e.g., increase of mucus; swelling of mucosa (Laache, Case 8); punctiform hæmorrhages and submucous hæmorrhages (Eichhorst, Case 4); small-celled infiltration around the follicles with increase of fibrous tissue; fatty changes in the glands, and atrophy of the glands (Fenwick, Nothnagel, Nolen, Hunter, Mader, Weichselbaum, Holt, and Nonne). The usual absence of naked-eye changes of congestion is to me in no way surprising when the extraordinary bloodless condition of the tissues and organs in this condition is borne in mind. I conclude that microscopical examination alone is reliable in determining the presence or absence of lesions.

The changes found in the intestinal mucosa from time to time are, I find, of a closely similar character—hyperæmia, "the mucosa of the intestine, the upper part of the jejunum, the lower part of the ileum, and the whole of the colon œdematous and swollen, with small hæmorrhages on the edges of the villi" (Eichhorst, Case 3).

Œdema; enteritis; erosion; ulcers; and thickening.—"Cæcum œdematous; one or two blackish small spots on the mucous membrane almost diphtheritic-looking" (Hale White, Case 13). "Large intestine; numerous cicatrices of ulcers, or ulcers newly healed, and a little recent diphtheritic inflammatory exudation in parts" (Ibid., Case 3). "Some patches of injection of ileum, and the mucous membrane of the large intestine irregularly injected" (Hale White, Case 20). "Chronic fibrotic changes in the colon with more recent hyperæmia and superficial necrosis" (Morley Fletcher).

VII.—RELATION OF THE GASTRIC INFECTION TO THE ANÆMIA.

It is clear from Case 8 that even during life there may be discoverable direct evidence of infective catarrh of the stomach. It is in connexion with this that the last case (Case 8) has for me such a particular interest, especially when taken in conjunction with Case 1. I had occasion in Case 1 to note the condition of the mouth and tongue and its variations as above described during life. In that case there were no stomach symptoms; but post mortem I found subacute chronic gastritis and atrophy of the gastric glands—a condition of the mucosa of the stomach, in short, identical with the subacute and chronic inflammation with atrophy noted in the tongue during life. In Case 8 there was an identical history as regards the mode of onset, the mouth symptoms (including also salivation), and the subsequent progressive anæmia. Here, however, I had an opportunity to examine the watery fluid without admixture with food brought up from the stomach; and I found evidence of a most intense infective catarrh, chiefly streptococcal—an infection of the stomach causing gastrorrhœa, probably of the same character as the trouble in the mouth which caused the salivation. The condition was clearly infective as was further shown by the effects of treatment. For both the gastrorrhœa and salivation, which had existed for five months, were in the course of a week brought incontinently to an end by the administration of salicylic acid as an antiseptic. Further, the infection thus arrested in activity had obviously some relation to the anæmia. For, following on its arrest, in a fortnight's time the red corpuscles rose from 1,290,000 (25 per cent.) to 2,200,000 (44 per cent.), a difference of 19 per cent.; while the hæmoglobin rose from 24 per cent. to 46 per cent., a difference of 22 per cent. I feel justified, then, in concluding that the infective catarrh in the stomach was not simply a complication resulting from the anæmia (blood-change); but that it really underlay and was responsible for the anæmia, since on removing it by direct antiseptic treatment there was so sudden and remarkable a recovery in the blood itself. In this case I conclude that an intense infection of the gastric mucosa similar to the infection in the mouth underlay the *pernicious anæmia*; and that the progressive *anæmia was not due* to the stomatitis or the glossitis, or even to the catarrh of the stomach *per se*, with their attendant disturbances of nutrition, but to the special infection which underlay and was the *cause of them* all. The stomatitis and the gastritis were the local lesions of an infection, probably of a "mixed" character, chiefly coccal—the progressive anæmia being the result of the destructive action of the poisons absorbed into the blood.

VIII.—ETIOLOGY.

I have now to consider the probable source of the infection pointed to by the preceding *observations*.

On this point the evidence available is extremely limited, confined as it is to the observations on the seven cases which I have described. For the disease has hitherto been examined and studied *solely* with reference to its relations to the usual causes of anæmia—such as loss of blood, pregnancy and childbirth, wasting discharges (diarrhœa), bad nourishment, and unhealthy surroundings. It is under these headings that its etiology has been discussed and beyond these nothing further has been investigated.

General etiology.—To my own mind no fact stands out more clearly in connexion with the etiology of the disease, than that none of the above conditions can of themselves produce the disease of pernicious anæmia with all its characteristic destructive blood changes. In the first place, I would point out the confusion which exists as to the importance of these so-called "causes." The same conditions—e.g., diarrhœa or vomiting—are arbitrarily regarded as causes or as effects, according to their prominence or to the judgment of the observer. Sometimes they are regarded as both cause and effect. This is well illustrated, I consider, in the grouping adopted by Eichhorst and since generally accepted. Eichhorst grouped his cases (91 in number) etiologically under two headings: 1. "Secondary" pernicious anæmia (67 in number) caused by (1) pregnancy and childbirth, 29; (2) vomiting and diarrhœa, 24; (3) loss of blood and discharges, 7; and (4) unhealthy surroundings, 7. 2. "Primary" pernicious anæmia (24 in number) where no cause was discoverable. The impression which this grouping naturally conveys is that in only 24 out of 91 cases were diarrhœa and vomiting of such a prominence as to excite attention or be regarded as causes. Nevertheless, on examination of the records of the remaining 43 cases of Group 1 assigned to other "causes," I find that either vomiting or diarrhœa, or both, sometimes uncontrollable in degree or other gastro-intestinal disturbances, were prominent features in no fewer than 34 cases—just as prominent, indeed, as the special condition selected to be the "cause." In other words, a total of 58 cases out of 67 (86 per cent.) might have been as reasonably assigned to gastro-intestinal disturbance as to other "causes." And even with regard to the 24 cases of Group 2 which he regarded as "primary," I find digestive troubles, diarrhœa, and vomiting, sometimes very marked in degree, in no fewer than 16 cases (67 per cent.). These facts appear to me to be interesting—not that in my judgment they point to gastro-intestinal disturbance any more than to pregnancy or the other stated conditions as the "cause" of the disease, but that they denote the unsatisfactory character of our present knowledge of the real "etiology" of the disease. When it comes to be a mere question of degree, whether a condition is considered to be a cause or a mere symptom of one and the same disease, it is obvious that knowledge is unsatisfactory. My own conclusion I have already stated—viz., that in all cases these gastro-intestinal disturbances, however slight or however prominent, are of the same character as the blood changes—viz., effects of the disease underlying the anæmia. The whole question of the etiology of the disease, in my judgment, is thus, so far as these above factors are concerned, a completely open one.

The infective nature of the disease: the source of infection.—The facts above recorded appear to me to denote the *infective*, as distinguished from the *general*, nature of the disease. Moreover, they denote the infection to be a *local*, not a *generalised*, one. It is confined to the alimentary tract, its chief seat being the stomach; no part of the alimentary tract from the mouth to the anus, however, being safe from it.

---

[1] A Study of 50 Cases of Pernicious Anæmia. Boston Medical and Surgical Journal, 1896, pp. 104-107.

Further, in certain of the foregoing cases the first site, or one of the first sites of infection has apparently been the mouth, general discomfort or soreness or tenderness of the mouth having been complained of either before the anæmia declared itself, or "at the same time" as the anæmia. There remains, then, the question whence the infection has sprung in the first instance—from without, or from within the mouth? In this relation the cases divide themselves into two groups—two cases in which there was a most definite history of exposure to sewer gas or drain influences (Cases 1 and 8); five cases in which no such history could on very careful inquiry on the point be traced. This failure to trace any source of outside infection need not necessarily denote that no such infection had occurred; for such failure is common at times with regard to nearly all infective diseases So clear is the history of exposure in the two cases mentioned, that in the absence of any other facts I should be disposed to regard the others as having possibly arisen in some similar although unrecognised way. But both in these two cases, and in the other five, there was the condition observed of either antecedent or coexisting marked dental cario necrosis—in most of the cases to such a degree as to amount to "neglect," the teeth being very carious in whole or in part. In the light of what I have described with regard to the infective nature of such dental conditions, and the possible effects on the stomach which may ensue, the question thus raised is whether the "mixed" infection underlying the disease may not have taken origin itself within the mouth in connexion with the teeth Or, at least, whether the infection may not have found its first footing, so to speak, amidst the infective septic conditions prevailing around the diseased teeth. Either alternative is possible. The subsequent course of the infection is then determined by the relative amount of resistance offered by the mucosa of the mouth and stomach respectively. In the great majority of cases the mucosa of the latter is the first to be affected—in certain cases possibly the only part to be affected. But in certain cases direct infection of the mucosa of the tongue and of the mouth also takes place—if one may judge from the foregoing data (which, however, as I have said, are probably too low) in at least 10 per cent. of cases.

It will remain for future observations on a larger series of cases to determine more precisely the points I have raised—viz, (1) whether dental decay is only important in creating the catarrhal conditions of the mouth and the stomach favourable for the later special infection; or (2) whether the special infection may not, so to speak, be created around them in the first instance; or (3) whether direct infection of the stomach can occur from simple exposure to infection (drain smells) independent of any oral or dental trouble Whichever may prove to be true, the fact of importance clear to me is, that dental and oral conditions in this disease deserve more attention than any hitherto bestowed upon them. This persistent overlooking of dental conditions I can perhaps best illustrate by my own experience—viz, that while actually interested in conditions of glossitis and stomatitis in cases of pernicious anæmia, it was eight years before I began to note especially the condition of the teeth.

Nature of the infection —I have throughout spoken of the infection as a "special" one, most probably of a "mixed" character—i e., brought about by the joint action of two or more organisms That it is no ordinary one—due, for example, to the ordinary organisms of the mouth or of dental decay—is clear from (1) the rarity of the disease, (2) the remarkably hæmolytic action of its poisons, and (3) the occurrence of an ordinary infective gastritis without any of the blood changes of pernicious anæmia (Case 7). That it is of a "mixed" character appears to me probable from two classes of facts. 1. The abundant presence (as in Case 8) of organisms of coccal and short streptococcal nature, forming zooglœa-like masses amidst the catarrhal and inflammatory exudation contained in the vomit These organisms were obviously related to the anæmia, the salivation, and the vomiting, since by administration of salicylic acid the first was greatly ameliorated and the two latter were abolished; and yet they are not such as are peculiar to this disease, but resemble cocci present in the stomach in other diseases. Unfortunately to the first (and as it turned out the only) specimen of vomit which I obtained I added formalin to preserve it, so that no bacteriological examination was possible. 2. The disease, though very rare in incidence, is nevertheless common to all classes irrespectively of station, mode of life, food, previous health, or general surroundings. It must remain for future observations to determine the nature of the organisms concerned and their relative rôle.

As it happened, a few days before this paper was sent in I learnt from Professor Adami of Montreal of some interesting and suggestive observations recently made by himself and his fellow-workers, Dr. D. Anderson and Dr. Ford, and while this is passing through the press I have received (Jan. 31st) his paper[2] Their observations may prove of importance in this relation, suggesting as they do that possibly the colon bacillus may be concerned as a secondary factor in the gastric change They have examined bacteriologically the contents of the stomach in four cases of pernicious anæmia They found (1) a complete absence of hydrochloric acid, with the presence, however, of considerable quantities of lactic and some butyric acid; (2) an abundant presence of the colon bacillus; (3) in one case a modified form—diplococcoid form—of the colon bacillus within the walls of the stomach; and (4) the presence of the same forms in the liver cells—the bodies giving the iron reaction and constituting, indeed, according to Professor Adami, the granules hitherto regarded as pigment granules With this last-mentioned conclusion (one, I think, of a debateable character) we are not here specially concerned. The matter, however, is otherwise with the second observation as to the presence of the colon bacillus in the stomach and its possible relation to the disease. On this point Professor Adami is "very careful not to state that the colon bacillus is the primary or the essential cause of (either cirrhosis of the liver or) pernicious anæmia." Indeed, he says that it is "probably not. In either case there is some primary or underlying factor favouring its entrance into the economy." The relation, indeed, is one he describes by the term "sub infection"—"a condition in which as a consequence of chronic inflammatory disturbance in connexion with the gastro-intestinal tract there may for long periods pass in through the walls of the stomach or of the intestine a greater number of the ordinary bacteria inhabiting the tract, and while the bacteria undergo the normal and inevitable destruction by the cells of the lymph glands, the liver, the kidneys, and other organs, nevertheless the excessive action of these cells and the effect on them of the bacterial toxins liberated in the process of destruction may eventually lead to grave changes in these cells and in the organs of which they are part—changes of a chronic nature" For the action of the bacillus Professor Adami, it will be seen, predicates the existence, "in the first place of some chronic inflammatory condition of the mucous membrane of the upper gastro-intestinal tract, leading often to atrophy"—the very condition, in fact, which according to my observations is found, but which I regard as one of the concomitant effects of the special infection underlying the anæmia. It will remain for future observations to determine what are the relative rôles respectively of the colon bacillus infection described by Professor Adami and the coccal and streptococcal infection found by myself in producing the gastritis

IX.—DEFINITION OF THE DISEASE.

For reasons above indicated I consider the terms "secondary" and "primary" used in connexion with the disease to be no longer fitly applicable To say that the disease is secondary to diarrhœa is just as correct, in my judgment, as to say that typhoid fever is secondary to the diarrhœa which attends it; for in both diseases the relation of the diarrhœa is the same. Hitherto the feature of the disease to arrest chief attention has naturally been the *anæmia*, the progressive blood change; and all other symptoms have been studied in relation to this The disease has been regarded as an anæmia complicated from time to time by other disturbances, digestive, nervous, circulatory, &c. The result has been to obscure some of the chief characters of the disease, and certainly to hide much of their proper relation to each other For the future it will conduce more to throw light on the disease if it be studied as an *infective disease characterised by anæmia* with *definite local and general* effects, than if viewed as an anæmia occasionally complicated with such effects.

---

[2] On Latent Infection and Sub-infection and on the Etiology of Hæmochromatosis and Pernicious Anæmia. The annual address before the Society of Internal Medicine, Chicago, Nov 29th, 1899. Journal of the American Medical Association, Dec. 23rd, 1899

Definition of the disease.—The definition I formulate for the disease is, then, the following. Pernicious anæmia, a chronic infective disease localised to the alimentary tract; *caused by* a definite infection of certain parts of the mucosa of the alimentary tract, chiefly of the stomach, occasionally also of the mouth and of the intestine. It is characterised by (1) intermittent destruction of blood and increasing anæmia (and all the other pathological and clinical changes consecutive to these—e g., anæmia, lemon colour, urobilinuria, hæmorrhages, dyspnœa, palpitation, œdema), as the result of the absorption of poisons into the blood; (2) periodic disturbance of the alimentary tract, chiefly of the stomach and the intestine, as local effects of the infection on the alimentary canal; and (3) occasional "toxæmic" attacks characterised by fever, sweatings, general nervous symptoms; not infrequently by effects—e g., numbness, tingling, ataxia, absence of reflexes—denoting deeper nervous changes, such as peripheral neuritis, sclerosis of the cord.

X.—TREATMENT.

The foregoing conclusions suggest certain additional considerations with regard to treatment. In my former paper the indications for treatment I considered to be two—(1) to remove the cause, with the attendant gastro-intestinal conditions favouring its operation; and (2) to combat the individual symptoms. With regard to the first indication it appears to me possible, with additional knowledge gained from the preceding observations, to fulfil this indication much more fully than has hitherto been the case, and that in two directions—first, with regard to the prevention and the removal of the cause, and, secondly, with regard to the conditions favouring its operation.

The prevention and removal of the cause.—The result of the foregoing observations has been to locate this infection underlying the disease definitely to the stomach, and to trace its source either to infection from without, or to the mouth itself.

1. *The hygiene of the teeth and mouth.*—I consider it, then, all-important in all cases of commencing anæmia that special attention should be directed to the condition of the teeth; and that even more than ordinary care should be taken with regard to their health, by removal not only of old stumps, but also of all black teeth and of teeth showing commencing cario-necrosis. Moreover, I consider these precautionary measures necessary, irrespectively of any statements made by the patient as to the degree of discomfort which his teeth are causing. As a matter of fact, in no single case above recorded, however bad I found the teeth to be, was my attention drawn to the teeth by the patient, or was any complaint made of them by him. Discomfort and pain in the teeth are the results of local inflammatory reaction—periostitis and gingivitis; and to a certain extent they denote relatively healthy conditions, inasmuch as they denote that the local tissues still have the power to react more or less actively to irritation. There is a stage, however, in pyogenic conditions, as, indeed, in other forms of infections, when local reaction is absent, or at most insignificant, at the very time when the general septic effects are most marked. The hygiene of the mouth deserves, therefore, in this disease the most scrupulous attention, irrespectively of the statements or opinions of the patient. Absence of local pain and discomfort in the teeth are no criterion, then, in my judgment, of absence of general septic effects (if their condition be recognisably bad).

2. *Local treatment of the stomach.*—As I have shown, whatever may be the source of the infection, its chief seat is invariably the stomach; and the first effect of the infection is an infective catarrh, followed later by deeper-seated changes of the nature of glandular atrophy and gastritis. The indications here are to remove or to combat this catarrh. This may be done either by *washing out the stomach*, as suggested by Sandoz, on the view that many of the symptoms of the disease are due to abnormal fermentation of food products within the stomach; or, still better as I conceive, by *administering local antiseptics* to diminish or to destroy the infection underlying the catarrh. In my former paper I suggested the use of intestinal antiseptics to combat the intestinal condition. The gastric conditions appeared then to be of a too deep-seated character to be affected by such local measures as washing out the stomach; nevertheless, it was one which I conceived might be adopted with advantage in the earlier stages of the disease at least. In the light of the present observations showing the active infective nature of the catarrh, I am more than ever of this view; but the advantages to be got are necessarily limited. We are not likely to remove an infection of the gastric mucosa by washing out the stomach, any more than we can hope to cure a stomatitis or glossitis by rinsing the mouth. In the case (Case 8) in which there was such salivation and gastrorrhœa I had it in mind to try washing out the stomach; but before doing so I determined to try the effect of the other line of treatment—the use of local antiseptics. The result to me was surprising. The antiseptic I used was the one that had proved so successful in Case 7 against ordinary infective gastritis—viz., salicylic acid. I selected this drug on general grounds as the antiseptic which appeared to me at once the most powerful and the least harmful, and the result was eminently satisfactory. Improvement was noticeable on the first day; salivation and sickness ceased from about the fourth or fifth day; and there was a remarkable improvement in the blood condition in two weeks' time as I have described. There are many other antiseptics of the same character which may prove to be equally beneficial. The one which I have been in the habit of using constantly is salicylate of bismuth, and with it also I have hardly ever failed to get some improvement, although never so marked as with salicylic acid.

3. *Local treatment of the intestine.*—In the cases where the symptoms point to intestinal rather than to gastric irritation a similar treatment should be adopted—use of intestinal antiseptics, as I before recommended—e g., salol, naphthol, calomel, or mercuric chloride (Case 2). In cases where the symptoms point to the colon or the rectum this may be supplemented, as I now recommend, by enemata containing salicylic acid.

4 *Medicinal treatment.*—These measures should not replace but should supplement the use of arsenic as heretofore, the great value of this drug, first used by Dr. Byrom Bramwell, being now fully established.

5. *Serum treatment.*—It is obvious, however, that if once the infection gets firmly rooted in the mucosa, mere local antiseptic treatment—however much it may benefit by diminishing or removing catarrh and thus arresting the disease temporarily—may fail to arrest it permanently, even when aided, as when possible it ought to be, by the use of arsenic. The only indication for treatment, then, is to combat the action of the poison on the blood after its absorption. To this end I propose in future to give a sustained and systematic trial to a serum treatment based on the results above stated. There are few diseases, if, indeed, any disease, in which we have such evidence of a local action on the blood as that which we possess in the case of pernicious anæmia. The chief ill effects of the disease are due to the progressive blood destruction, and its consequent anæmia. If we could eliminate this local action on the blood, or counteract it, the disease as a disease would lose its characters. Its infection would be interesting as a cause of stomatitis, of gastritis, of possibly some form of enteritis, with their attendant symptoms, but it would not cause the anæmia which it now does. I propose, then, to try the effect of systematic serum treatment. The nature of the serum I shall reserve for later investigations accurately to determine. For the present I propose to try the effect of antistreptococcic serum, inasmuch as my observations point to pyogenic organisms as always at least part agents in the infection. In suggesting this treatment I desire to emphasise that its trial is based, not on any hypothetical considerations as to the nature of the anæmia, but on a series of observations, extending now over 15 years, which slowly, step by step, have served to trace the anæmia back to an infection arising in connexion with the alimentary canal. I have purposely refrained from suggesting such treatment, or from trying it, till I was in possession of facts which appeared to me conclusive as to the infective nature of the disease, and till I had definitely formulated, as I have now done, the grounds of my conclusions.

APPENDIX.—CASES.

CASE 1.—In this case of pernicious anæmia there was a history of "gastritis" six years before. The origin of the illness was referred to an exposure to insanitary conditions, accompanied at the time by irritable sores under the tongue. The teeth were loose and the gums were spongy. Retching and vomiting, which at first prevailed, were subsequently absent. There were well-marked febrile attacks, with perspirations and urobilinuria. The duration of illness was three years. Post mortem there was well-marked chronic and subacute gastritis[8] The patient was a man, aged 59 years, who was seen in June, 1888 The health of the patient had previously been good except that in 1883 he was under treatment for a short time for some gastric affection termed "gastritis" (The patient was seen by Sir George Paget) The present illness dated from 1886 During a holiday he had been exposed for a time to unhealthy sanitary conditions and had suffered at the time from sore throat and diarrhœa From that time onward he never regained his former health, but continued to suffer at times from an inflammatory condition of the throat and tongue and gradual failure of strength Late in 1887 he sought medical advice In January, 1888, the anæmia was already very marked (red corpuscles 870,000), and at times there were retching and vomiting, especially in the morning; congestion of the throat and certain pale red spots on the tongue were also present (The patient was seen by Sir T Lauder Brunton) He was first seen by me in June, 1888 Considerable recovery had taken place There was great weakness but no emaciation, profound pallor but no trace of lemon tint or of jaundice The condition of the tongue troubled him much There was great tenderness especially when hot or stimulating food or drinks of any kind were taken The organ was extremely raw and flabby, deeply indented by the teeth, red and fiery in appearance, with here and there scattered inflamed patches Its mucosa was smooth as if devoid of papillæ There was inflammatory redness over the anterior pillars of the fauces There was no uneasiness or tenderness or other symptoms connected with the stomach itself The red corpuscles of the blood numbered 3,200,000, hæmoglobin, 56 per cent The improvement was maintained till August, 1888 Then there was increasing weakness till the patient was confined to bed in December On March 9th, 1889, he was again seen by me There was extreme pallor with slight lemon colour but no fever The pulse was 108, soft and regular The weakness was very great, the patient being unable even to sit up for any time The appetite was very poor, there was no desire for food and much discomfort in taking it, especially if the food was hot or stimulating The gums were very spongy and some of the teeth were loose The tongue was much the same as before but not quite so raw looking It presented a more atrophied appearance, the mucous membrane was smooth and free from papillæ At the parts over the dorsum and along the edges were patches of more fiery redness, some under the tip of the tongue showing small inflamed vesicles full of serum. The whole tongue was tender and mastication was difficult In connexion with the stomach there was no acidity or uneasiness after food The bowels were irregular, at times there was looseness, especially at nights, alternating with constipation While the former condition weakened him the latter occasioned even more discomfort He always felt very uneasy when the bowels were not moved daily Of red corpuscles in the blood there were 1,730 000 (34 per cent), hæmoglobin 30 per cent As regards the nervous system there were sleeplessness at night and occasional and somewhat profuse perspirations, especially in the early morning; the latter were usually connected with the looseness of the bowels at such times The subsequent history of the case was as follows On March 10th astringent lotions for the mouth were used and a diet of milk and farinaceous food was ordered Two minim doses of liquor arsenicalis were ordered in addition to the iron which the patient was already taking On March 20th there was improvement The tongue had lost its angry red appearance, it was much paler, the inflamed patches were less marked, and the vesicles had disappeared From this time onward till the death of the patient on May 22nd the tongue gave him no further trouble, its condition being better than at any time during the previous one and a half years It always presented a smooth, flabby appearance, but the tenderness on eating had been entirely lost, instead of it being a painful effort to take even bland food he could take all kinds of food and even condiments without the slightest discomfort The periodic "toxæmic" attacks were without any recognisable exciting cause, and were always marked by certain features Thus, two days previously to the seizure of March 22nd more lemon tint than usual was noticed and the urine was more highly coloured On the night of the 21st the patient had been disturbed by perspiration, but feeling better on the morning of the 22nd he took his breakfast as usual Shortly afterwards he was seized with a feeling of intense weakness and with drowsiness so marked that at the time of my visit he lay as if partially narcotised, answering questions slowly and languidly (his natural disposition was lively and excitable); there was a ghastly lemon hue, the pulse was rapid, the temperature was 99 4° F, and the pupils were contracted The drowsiness continued till late in the afternoon, gradually passing off During the night there were several free motions of very dark colour and the urine on the next day was of a remarkably high colour There occurred similar attacks from time to time—April 13th, 17th, and 24th. On the day following such an attack the patient always expressed himself as relieved, although it always left him much weaker No ground was regained after the attack on April 24th Death took place on May 22nd. Post mortem there were characteristic pigment changes in the liver and the kidneys The walls of the stomach were very thin and wasted, but there was no trace of malignant disease The lymph glands in the smaller curvature were enlarged, soft, and pinkish, the largest of them being five centimetres in diameter The stomach was empty, its mucosa was covered with a thin layer of mucus, and it was bile-stained near the pylorus The mucous membrane was very thin, presenting no obvious morbid change Microscopically there were well marked changes in the mucous and submucous coats of the cardiac end, atrophy of the gastric glands, and an increase of fibrous tissue At others the glands were still seen to be surrounded by foci of granulation tissue Around these inflammatory foci bloodvessels dilated extending in from the submucosa. The submucous coat was greatly thickened as the result of chronic inflammation, its thickened vessels in parts showing subacute inflammatory changes There were no inflammatory changes at the pyloric end In the intestine there was nothing abnormal

CASE 2 —The origin of illness in this case of pernicious anæmia was referred to the use of a new tooth plate Sickness, looseness of the bowels, toxæmic attacks, and nervous symptoms were the presenting conditions The illness lasted for four and a half years The patient, a man, aged 42 years, was sent to me by Dr R Honeyburne of Idle, Bradford, with the following graphic history of the case "He began to look paler nearly four years ago and consulted me then He dates his illness himself from a new set of upper teeth fixed in a gold plate which tarnished and tasted 'like pennies' from the first day he wore them, until by my advice they were removed and a vulcanite plate substituted In addition to a general feeling of ill health one of the first symptoms he complained of was a sensation of numbness and tingling in his hands and feet He became progressively more and more anæmic, lost his knee jerk, developed hæmic murmurs, vomited his food, and certain of his muscles (deltoids and extensors of the thigh) wasted markedly There was no wrist drop By this time his pallor was most marked, his skin having a yellowish tinge, his pulse got quicker and weaker till he lay in bed œdematous nearly all over (on the chest, back, legs, backs of hands, face, &c), he was delirious, vomiting nearly everything, his blood being pale and on examination containing very few perfectly formed cells and a mass of granular débris—in short, he got so bad that I did not think he could live another week All this time he had been taking large quantities of iron and latterly arsenic An addition of one twenty fourth of a grain of corrosive sublimate was now added to his medicine (five minims of liquor arsenicalis every four hours) and his improvement under it (or at any rate after it) was marvellous The vomiting stopped, the œdema subsided, and he began to gain colour In about three months he was quite well again with the exception of the wasted muscles which still remained stiff and made his gait somewhat awkward They in about six months more had also recovered except the knee jerk At this time looking back on the case I thought it one of lead poisoning though Dr J E Eddison of Leeds then leaned to the view that it was a cured case of pernicious anæmia The patient remained well for two years, then he had an attack of melancholia, which soon passed off, leaving him again quite well (better in health than he had ever felt before, so he says) There was no anæmia This state of well being lasted for about six months when small pox being prevalent I vaccinated him This occurred last October (1893), and from that date he gradually declined in health until about Christmas, when his anæmia was well marked and he began to take his former chloride and arsenic He immediately so until he had an attack which looked like influenza, but may have been one of the febrile attacks common to the disease, since which time he has remained nearly stationary in spite of the medicine he has been taking regularly, with the exception of a short time when we were obliged to remit it because of an attack of arsenic poisoning—scaly eczema on the backs of the wrists and elbows, with marked bronzing of the skin in other parts. I think that is about all I have to tell you concerning his history. If there is anything else you want to know he will be able to give you an intelligent account of it himself. With regard to my theory of lead-poisoning I must say that I was never able to find any possible means of lead ingestion except the doubtful one of the tooth-plate; also, about the vaccination origin of the relapse, it occurred exactly in point of time, but I never heard of such an origin of pernicious anæmia. Still, it is a disease of which we have much to learn." The family history of the patient was good and his own previous health had been good. The present illness dated from four years previously to my seeing him (May, 1894) He had changed his tooth-plate in May and had suffered from acidity and a pricking feeling in the hands; in December he began to get weak. In January, 1891, he had to take to his bed for six weeks, with great weakness, swelling of the hands, sickness, and constipation. He was "unconscious for a week." He woke up suddenly conscious and asked for a glass of beer. He could eat anything and he got well and in June was going about; there was, however, stiffness in the legs and the muscles were wasted. He remained well till early in 1893, when he had business worry, not a great one, but it seemed to "knock all the nerve" out of him. He went away for three weeks and came back better. During that summer (1893) he had never had such good health. His usual weight was 13 st. 6 lb.; it then rose to 13 st. 12 lb., now in May, 1894, it was 11 st. 6 lb. In December, 1893, came the small-pox scare. He got frightened and was vaccinated. Two weeks later he had sickness and he suffered from biliousness. After being three weeks under treatment he again got well, or seemed to do so. In January, 1894, he had a sudden fit of chilliness—a rigor. The temperature was 102° F. The patient, who was ill for two days, got well from this, but he "hung fire" ever since. In May, 1894, he was sallow, lemon-coloured, very weak, and breathless. He complained of numbness and tingling of the legs, and there was marked bronzing of the skin over the back and in patches on the legs. The knee-jerks were absent. He suffered a good deal from sickness, which came on irregularly morning, afternoon, and evening, and was sometimes bilious in character. The bowels had been very free, acting two or three times daily up to a week previously to the time of my seeing him. There was no pain or loss of blood. The red corpuscles in the blood numbered 1,800,000 (36 per cent.) with poikilocytosis; hæmoglobin, 38 per cent. The patient died in December, 1894, after an illness of four and a half years' duration.

---

[8] rit Med Jour, vol i., 1891

CASE 3—This was a case of pernicious anæmia of indefinite origin. There were febrile attacks, sickness, and biliousness, and the tongue was raw and tender, "like raw beef." The duration of the illness was two years. The patient, who was seen on Oct. 10th, 1895, was sent to me by Mr. Corner of Poplar His previous health had been good. Two years before (1893) he had suffered from "influenza." A year later (1894) he had had another attack. He did not suffer from indigestion before his first influenzal attack in 1893. After that he constantly complained of a faint and weak-feeling stomach. Since then there had been loss of appetite for both food and drink. From Christmas (1894) to May (1895) there was improvement, when he went back to work, at which he continued till the middle of August. He was still, however, very weak, as he noted as a mark of improvement that he could walk a mile or so. His appetite at this time was fair. On Sept. 7th he was seized with a chill and with shiverings. The temperature was 104° F. On the next day the temperature was normal. He picked up a little and went to business, but grew feebler day by day. He felt sick and fainted at times. On Oct. 10th, 1895, his condition was extremely anæmic, the lemon hue was noticeable, and there was slight conjunctival jaundice. He had lost 1½ st. in weight in the last 12 months. There was sickness occasionally, usually after eating. The stomach was slightly dilated; there was no tenderness but some flatulence. The bowels during the past year had been regular; formerly they were constipated. There was no pain or discomfort in, or loss of blood from, them. The rectum was normal. Between October, 1894, and May, 1895, the tongue was raw and tender "like raw liver," causing him great pain. He had bad teeth, but they caused him very little pain. He was scarcely ever known to have toothache, but now and again he suffered from neuralgia. Latterly he would discover that a tooth was loose and could be drawn out without the slightest force or trouble. He never wore false teeth or a tooth-plate of any kind. The red blood corpuscles numbered 1,860,000 (37 per cent.), with slight poikilocytosis; hæmoglobin, 54 per cent. There were no retinal hæmorrhages. There was a sensation of numbness and tingling in the fingers. The patient died in January, 1896. Mr. Corner reported that "he had acute relapses of fever, with disturbances of liver, &c., and increased failure of heart." From when I saw him up to the time of his death he suffered from sickness and vomiting. During the last month or two of his illness the faint and weak feeling in his stomach he described as agony.

CASE 4.—In this case of pernicious anæmia there were nervous symptoms, the teeth were all decayed and black, and there was diarrhœa but no sickness. The illness lasted for two and a half years. The patient was a man, aged 56 years, whom I saw with Dr. Aldren Turner on Jan. 24th, 1896. There was a history of increasing weakness with intermittent periods of betterment for the previous two and a half years, the weakness specially marked during the last three months. The patient had come under Dr. Turner's care on account of nervous symptoms, ataxia, numbness and paræsthesia, and loss of knee-jerks, but there was no loss of flesh. He had formerly been a very active, athletic man. When seen he was slightly built and appeared to be very anæmic and slightly lemon-coloured. The tongue was soft, clean, moist, and not indented. The teeth were very bad, all decayed; they formed a lot of black decayed fangs and crowns. The stomach was dilated and there were splashing sounds; the abdomen generally was flatulently distended and full. Flatulence was present but there was no sickness. The bowels were loose, acting five or six times daily, and the stools were very offensive. There was no malignant disease in the rectum. The blood was exceedingly pale; the red corpuscles, which numbered 760,000 (15 per cent.), were small and misshapen and there was much granular débris; hæmoglobin, 18 per cent. Systolic bruits were heard in the heart. There was some œdema of the ankles. The pulse was 84, of fair strength, and regular (the patient had been taking digitalis). He was extremely excitable, talking almost incessantly, and was very difficult to manage. The colour of the urine was normal; there was no albumin. The spleen was not enlarged. By way of treatment as much milk as possible was given, five grains of salicylate of bismuth with five grains of salol were administered every four hours, five minims of liquor arsenicalis thrice daily, and calomel at night for three nights. On Feb. 3rd (ten days later) I learnt that he had been better since my former visit, but had been very weak for the last two days, with weak, intermittent, and irregular pulse. He had been very excitable, seeing visitors, altering his will, and constantly talking. He had become hoarse. His colour was better and his fingers were warmer. The abdomen was much less distended and was soft; there was no splashing. In that respect the patient had felt much better. The tongue was clean and moist. The bowels were still loose and had acted three times during the night; the stools were no longer offensive and they were not so coloured (they were black before but now they were of the colour of the yolk of an egg) The pulse was 84, soft, and regular. The blood showed notable difference in colour. Red corpuscles, 1,250,000 (25 per cent.); hæmoglobin 40 per cent.; there was no granular débris. The hoarseness formed the prelude to an attack of bronchitis from which the patient died a week later.

CASE 5—This was a case of pernicious anæmia of ill-defined origin. There was hæmorrhoidal loss of blood but there were no gastric symptoms. The teeth were necrosed. The duration of the illness was two years and eight months. In company with Dr Rowland Coombs of Bedford I saw the patient, a man, aged 51 years, on Feb. 8th, 1896. He was a healthy man who had never suffered from any severe illness till the present one. There had been increasing weakness for the last 12 months, especially for the last four months, and for the last week he had been confined to bed. He was very pale, with slight lemon colour of the skin and slight conjunctival jaundice. He had never suffered from indigestion, sickness, or vomiting, and was free from them now. At most there was only a slight degree of flatulence. The tongue was clean, but not especially smooth, and there was nothing abnormal. There were two or three exceedingly bad, black, rotten stumps of teeth in the lower jaw. The bowels were regular and there was no diarrhœa. The weakness was greatest, almost to faintness, when the bowels were moved. He had suffered a little from piles, which used to bleed, two or three years previously but not at this time. There was no trace of malignant diseases in the rectum. The abdomen appeared somewhat full and there was considerable distension of the colon, especially of the transverse colon, but nothing abnormal was felt. In the liver and spleen the dulness was normal. In the heart loud bruits were heard. The urine was dark; an urobilin band could be detected. In the blood the hæmocytes numbered 1,230,000 (24 per cent.), with poikilocytosis; leucocytes, 4000 (1·307); hæmoglobin, 40 per cent. On May 8th, 1896, the following note was made by Dr. Coombs: "I think him much better. Looks better. His anæmia and breathlessness on exertion much improved. He still complains of rectal trouble, due wholly, I think, to hæmorrhoids. After a time I intend to propose to excise them, as the little loss of blood he suffers may be ill afforded in his case." A later note stated: "He has taken on a part of his work again and apparently without hurt." The patient died in December, 1897.

CASE 6.—This was a case of pernicious anæmia in which there was a history of chronic indigestion, very bad teeth, and diarrhœa. The illness lasted for nine months. The patient, a man, aged 52 years, was seen by Dr. A. H. W. Clemow of South Kensington and myself on Jan. 31st, 1898. He had suffered from anæmia six months previously and after getting better had experienced a relapse three weeks before we saw him. He had always been healthy but had suffered from indigestion, poor appetite, and a "bad cook." He was thin, spare, very anæmic, and of a light lemon tint. The tongue was clean but flabby. The teeth were very bad, all covered with tartar and sordes. Of three of the upper molars only the roots were left and one of these was loose and could be pulled out with the finger. Digestion was very feeble. The bowels were loose irregularly, and the breath was bad. The abdomen was sunken; there were no pains or tumour in the epigastrium. In the liver and spleen the dulness was normal. The urine was dark in colour with urates but no albumin. The red corpuscles in the blood numbered 1,390,000 (27 per cent.); hæmoglobin, 34 per cent.; there was poikilocytosis; there was no increase of leucocytes but an increase of granular material. The patient died on Feb. 12th, 1898. The following note was made by Dr. Clemow: "In the earlier attack of anæmia I find he had no sickness, but there was irregularity of the bowels with diarrhœa at times. When I first saw him his temperature was raised about a degree and pulse rapid, 112. Under iron these symptoms gradually subsided, but I had made a diagnosis of probable pernicious anæmia. During the last week of his illness everything he took into the stomach caused considerable pain."

CASE 8.—This was a case of pernicious anæmia in which the origin of the illness was referred to exposure to sewer-gas. The teeth were decayed and there were sores in the mouth. Intense gastrorrhœa was present with sickness and vomiting. Microscopical examination of the vomit pointed to intense mycotic catarrh. Dr Aldren Turner and I saw the patient, a man aged 53 years, on April 21st, 1899. He had been well till June, 1898, when for several weeks he was much exposed to sewer-gas during his occupation as a builder. It appeared that close to the window of an office where he worked there was a cesspool the smell from which was so bad that it often made him sick. He had lost flesh, but not much. By October he was too ill to work and was noticed to be very pale; he suffered from retching, vomiting, and pain after food. This continued. His complaint was thought to be cancer. He saw a physician, who put him upon a milk diet for a week or ten days and then on ordinary diet, but there was no improvement. When the patient was seen by Dr. Turner on April 11th, 1899, the chief symptoms were constant retching with salivation and flow of watery mucus from the mouth and periodical daily vomiting of still large quantities. The red corpuscles in the blood numbered 1,600,000 (32 per cent.); hæmoglobin, 28 per cent. No malignant disease was discoverable in the stomach or in the rectum. On April 21st the patient was very anæmic and he presented the lemon-coloured appearance. The pulse was 90 and the temperature remained steadily between 99° and 100°. There were hæmic murmurs. The red corpuscles numbered 1,290,000 (25 per cent.) with marked poikilocytosis; hæmoglobin 24 per cent. There were constant salivation and the bringing up of large quantities of watery mucus (pints daily), and during the periodical sickness of the patient still larger quantities were vomited. The stomach was dilated, but there was no splashing. The patient suffered from no pain, but from time to time he experienced a feeling of great discomfort with nausea which was relieved by vomiting large quantities of mucus, after which he felt easier and was usually hungry. Meats disagreed with him and gave him pain. The upper teeth were absent, except one in front which was dark, decayed, and loose in the socket. Several molars and bicuspids were absent in the lower jaw. The patient had worn tooth-plates for the last two years; previously the teeth had been in a bad condition. When the illness began in June, 1898, he had some sort of painful sores in the mouth under the tongue which were not connected with the teeth. His own description was that his illness seemed somehow or other connected with this—"it seemed to spread right down into the stomach and right through him." The liver and spleen dulness was normal. The specimen of the vomit which was obtained for microscopical examination was fluid with rusty flakes. There was alkaline reaction. The flakes were found to consist of mucus with catarrhal cells in great number, the whole being loaded with cocci, both within the catarrhal cells and in zooglœa-like masses. No yeast fungi were found to exist. A diagnosis of pernicious anæmia with subacute infective catarrh of the stomach ("mycotic catarrh") was made. The treatment consisted of the administration of from three to four pints of peptonised milk daily, liq. bismuthi sedativa (Schacht) with salicylic acid (three grains) thrice daily, mustard leaves over the stomach at night, and two grains of calomel at night. On April 28th Dr. Turner reported: "Under new treatment (commenced on Friday) improvement noticeable on Monday; since then steady and marked. Amount of fluid brought up much diminished; no vomiting since Tuesday; patient has lost sense of discomfort about stomach he has had for months; likes the milk. Improvement in colour very marked. Blood: red corpuscles, 1,600,000 (32 per cent.); hæmoglobin 40 per cent." On May 5th the patient was again seen by me. There was very marked improvement All of the stomach symptoms had gone and there was no further expectoration or vomiting, but I was unable to get any stomach material for another examination. In the blood the red corpuscles numbered 2,200,000 (44 per cent.); hæmoglobin, 46 per cent. The patient left for home three days later. The subsequent history of the case, for which I am indebted to the medical attendant (Mr. R. O. Kirkby), was as follows: "The vomiting and constipation improved steadily after he returned home, but the blood condition fluctuated, the highest count being about 3,000,000 red corpuscles. He developed acute epididymitis and orchitis in September while I was away for my holiday. This was followed by cystitis and albuminuria, the albumin being in excess of the amount attributable to pus. Œdema of the feet and legs followed and congestion of the bases of the lungs The urine became clearer during the administration of urotropine, but the patient had some attacks of syncope and gradually faded out on Dec. 3rd, 1899. The vomiting recurred three or four times after he returned home, but the intervals between the attacks increased and the matter vomited latterly was merely bile-stained milk. Salivation occurred when he had stomatitis. The latter was always a bother. The mouth was always clammy and uncomfortable. Diarrhœa occurred several times during the illness, the bowels being opened four or five times in the 24 hours, but usually the motions were formed, sometimes scybalous and coated with mucus; occasionally there were streaks of blood."

Harley-street, W.

BRISTOL DRAINAGE SCHEME.—Last week a poll was taken of the owners and ratepayers of Bristol on the proposal to promote a Main Drainage Bill, and by a majority of over 10,000 the proposal was rejected.

BARNSTAPLE AND NORTH DEVON DISPENSARY.—The sixty-eighth annual meeting of this institution was held on Feb. 1st. The report showed an increase in the number of patients treated. The financial statement showed that the funded stock was now £5768.

PROGNOSIS IN APPENDICITIS, WITH AN ILLUSTRATIVE SERIES OF 200 CASES.[1]

BY H. A. CALEY, M.D., M.R.C.P. LOND.,
PHYSICIAN IN CHARGE OF OUT-PATIENTS AND LECTURER ON MATERIA MEDICA AND THERAPEUTICS AT ST. MARY'S HOSPITAL.

DURING the last few years so much has been written and spoken about disease of the appendix that one hesitates to contribute another paper on such a well-worn theme. The subject of prognosis, more particularly the basis of prognosis in individual cases, is, however, by no means threshed out, and my object will be attained if the points now raised induce discussion as to the relative value of the available data. The discussion of questions of treatment is intentionally avoided, but a consideration of prognostic indications will serve indirectly to emphasise the essential importance of regarding "appendicitis" not as a defined entity, but as a group of conditions ranging from acute perforative appendicitis at one extreme to a mild perityphlitis at the other; and of recognising that careful differentiation is the only sure foundation of rational treatment—treatment based on the actual conditions present and not on routine lines—surgical or medical.

Any acute attack of appendicitis involves more or less immediate risk to life during the attack, and there is the well-known liability to recurrence at a subsequent period, so that the subject of prognosis may be considered in two sections: (1) prognosis as to recovery from the attack, and (2) prognosis as to subsequent recurrence.

I.—PROGNOSIS AS TO RECOVERY.

General statistics are in the case of affections of the appendix more than usually untrustworthy and are entirely valueless unless the survey is sufficiently wide to include all the forms of appendicitis, and unless care is taken to distinguish clearly between case-mortality and attack-mortality. The importance of including every type of case, mild or severe, is brought out in the series of 200 consecutive cases treated in the medical and surgical wards of St. Mary's Hospital which are here adduced to illustrate certain points. I desire to express my indebtedness to my colleagues, Dr. W. B. Cheadle, Dr D B. Lees, Dr. S Phillips, Mr. E. Owen, Mr. H W. Page, Mr. A. J. Pepper, Mr. A. Q. Silcock, Mr. J. E. Lane, and Mr. H. S. Collier for permission to include in the series cases under their care, many of which I have had opportunities of examining from this point of view. It must be clearly understood that any statistics here given are intended solely to illustrate certain points and are not to be regarded as in themselves a basis for deduction.

Ninety-eight cases were treated throughout in the medical wards with three deaths, and 102 were treated in the surgical wards with 22 deaths, a certain proportion of the surgical cases having been transferred from the medical side. The low mortality of the medical series is attributable to the large proportion of cases of simple perityphlitis (appendicitis with local non-suppurative peritonitis), just as the higher mortality of the surgical series is due to the large proportion of cases with general peritonitis which was present in 20 out of 25 fatal cases. When the two sets are grouped together we have a more representative series showing an aggregate mortality of 25 in 200 cases, or 12½ per cent—a figure which bears a general correspondence with the 14 per cent given by Mr. F. Treves as an approximate average for hospital cases. It is certain that hospital statistics give an exaggerated idea of the tendency to a fatal termination for the reason that many of the milder cases are not sent to hospitals, while the more severe forms with general peritonitis gravitate there, as the hospital surgeon who is called upon to operate on practically hopeless "too late" cases knows so well. Mr. Treves considers that if a large series, including both hospital and private cases, were taken together the mortality would be nearer 5 per cent. than 10 per cent.

Of much greater importance, however, than percentage mortality in the aggregate is the rate of mortality in the several types—a point emphasised by Dr H. P. Hawkins in his instructive series of 264 cases from the records of St. Thomas's Hospital. The necessity for careful differentiation lies at the very root of accurate diagnosis and therefore of prognosis; and any classification, if it is to illustrate these points, must be based upon the relationship between the lesion of the appendix and any resulting peritoneal or other infection, and not upon the pathological features of the lesion of the appendix by itself. In the following table the cases are grouped into five classes.

Class		Recovered	Died.
1	Simple appendicitis and perityphlitis	99	
2	Appendicitis with localised suppuration (operation in 27 cases)	29	
3	Appendicitis with diffuse peritonitis (operation in 17 cases)	3	20
4	Chronic and relapsing appendicitis (operation in 37 cases)	42	—
5	Appendicitis with special complications	2	3
		175	25
		200	

Class 1, simple appendicitis and perityphlitis, comprises a minority of cases in which the inflammation is almost or entirely limited to the walls of the appendix and a larger number of cases in which, as the result of the appendicitis, there is simple perityphlitis—i e., localised non-suppurative peritonitis of an adhesive type.

Class 2 consists of cases in which the appendicitis has resulted in localised suppuration, usually intra-peritoneal, sometimes retro peritoneal.

Class 3 comprises all cases of appendicitis resulting in diffuse as distinct from localised peritoneal infection. The term "diffuse peritonitis" is employed rather than "general peritonitis," because not rarely the peritonitis is limited, or nearly limited, to the lower half of the abdominal cavity.

Class 4 is made up of chronic and relapsing forms. Any case in which three or more attacks occurred is included in this class The individual attacks of relapsing cases resemble those of Class 1, but from the pathological and prognostic standpoints they have definite differential features.

Class 5 is a small and diminishing group consisting of cases in which the chief danger arises from complications other than those directly connected with peritonitis or local abscess—e.g., intestinal obstruction, fæcal fistula, suppurative pylephlebitis with portal or general pyæmia, hepatic or subphrenic abscess, thrombosis of the iliac vein, pleurisy and pneumonia, parotitis, or secondary hæmorrhage.

In the 200 cases of my series there were two of acute intestinal obstruction, three of fæcal fistula (all of which did well), two of hepatic abscess, one of subphrenic abscess, one of parotitis, one of acute pulmonary œdema after operation, and one of pneumonia; but only those in which the special complications influenced their course are included in Class 5.

With these general observations we may now pass on to the consideration of the principles of prognosis in an individual case. Prognosis must ultimately depend upon the precise nature of the lesion, which, in fact, constitutes the pathological basis of prognosis. Corresponding with the morbid processes we have various clinical manifestations, and the latter, in so far as they afford indications of what is actually taking place, constitute the clinical basis of prognosis.

THE PATHOLOGICAL BASIS OF PROGNOSIS

There are two essential factors in the pathological basis of prognosis: 1. The nature and course of the lesion of the appendix regarded from the point of view of relative infectivity. 2 The extent and nature of any resulting peritoneal infection which depends for the most part on the actual condition of the appendix and in part also upon its position and relations and upon any special modifying conditions such as the presence of old adhesions. The most important direct prognostic factor is the peritoneal, and it may therefore be considered first.

1. *The extent and nature of the peritoneal infection*—It is well known that, given a case of appendicitis, the danger to life in a very large measure hinges upon the extent and nature of the peritoneal involvement or liability to involvement In the large majority of instances when the disease is fatal the cause of death is diffuse infection of the

---

[1] A paper read before a meeting of the Medical Society of London on Nov. 27th, 1899.

peritoneum resulting in septic peritonitis. Thus, in 20 out of 25 fatal cases in my series there was diffuse peritonitis, frequently associated with local collections of pus in the vicinity of the appendix. It will be noticed that in the present series of cases the mortality in those with diffuse peritonitis was approximately 87 per cent. Many of these patients were in a practically hopeless condition when they were admitted. Some no doubt might have been saved by early operation. It will not be appreciably beside the mark if we conclude that where there is diffuse peritonitis the mortality will range between 80 per cent. and 90 per cent.—a conclusion which forces into prominence the necessity for attempting to anticipate by early operation such widespread infection.

Next to diffuse septic peritonitis, and putting aside such rare and fatal complications as suppurative pylephlebitis or hepatic abscess, the most formidable condition is local suppuration. It is, however, in connexion with this group of cases that the modern treatment of appendicitis has produced the most conspicuous benefit. For example, in my series, out of 31 cases with strictly localised suppuration 29 recovered, and it so happened both of the fatal cases were obscure cases with secondary abscess of the liver, and in one with general pyæmia also. In two out of the 31 cases the abscess ruptured into the bowel and was thus evacuated. Turning to Class 1 we see that when the lesion is of a strictly localised and non-infective type the prognosis, so far as immediate risk to life is concerned, is highly favourable—in this series and in Dr. Hawkins's series uniformly so. Whilst, however, the immediate risk to life from a localised adhesive peritonitis is very slight there are dangers of a more remote kind. Adhesions may persist leading to intestinal obstruction, which was the cause of death in two of the cases in Class 5, or permanent structural changes may be started in the appendix which sooner or later give rise to recurrent attacks—usually, it is true, only slight attacks, but occasionally, owing to the supervention of intense infective inflammation, of a grave type. Of Class 4, composed of chronic and relapsing cases, it is only necessary to point out that the individual attacks were for the most part of a mild type and that of 38 cases in which the appendix was removed all the patients recovered except one, who was an elderly man suffering from chronic appendicitis. He died three days after the operation from acute pulmonary œdema. This case is included in Class 5 Such facts as these are sufficient to illustrate that so far as immediate risk to life is concerned one chief factor is the extent and nature of the peritoneal infection, whether localised or diffuse, suppurative or non-suppurative, of mild or severe degree of virulence.

2. *The nature and course of the appendix lesion*.—From the point of view of prognosis we may divide appendix lesions into severe forms and mild forms on the basis of relative infectivity. Some forms of appendicitis may be regarded as mildly infective, others as severely infective, the distinction depending in part upon gross anatomical changes and in part upon the virulence of the infective organisms contained therein. As to the latter we have no certain data available for purposes of prognosis; on the other hand, it is comparatively easy to gauge the relative severity of the anatomical lesions of the appendix. Severe lesions of the appendix are: (1) perforation, whether from concretion, ulceration or gangrene; (2) gangrene (whether from interference with blood supply or from intense infective inflammation); and (3) ulceration, due to specific infections—e.g., tuberculosis, typhoid fever, dysentery, or actinomycosis, the presence of concretions, or the result of intense inflammation. Perforation, gangrene, and ulceration are those which possess in the greatest degree the property of infectivity, but to these we must add two others; (4) concretion; and (5) suppuration within the appendix itself, which, though they may exist for a long time without causing trouble, are potentially severe lesions. These severe lesions produce a relatively intense infection so that the outcome is in the most grave cases diffuse septic peritonitis, and in the less grave but still severe cases local suppuration. For example, of 18 cases of diffuse peritonitis 12 cases were associated with perforation and six cases with gangrene, both perforation and gangrene being in many instances secondary to concretion, and 10 out of 31 cases of local abscess were proved to be due to perforation or gangrene; in many of the remainder there was strong reason to suspect perforation. Mild lesions of the appendix are: (1) "simple" inflammation (catarrhal, or more correctly "parietal," appendicitis), acute or chronic; (2) stenosis or obliteration of the lumen, which is frequently associated with (3) cystic dilatation of distal portion; (4) concretion without ulceration; (5) superficial ulceration; and (6) kinking, adhesion, volvulus, or hypertrophy of mucosa, any of which may occlude the lumen. This group, while it consists of lesions which are comparatively mild from the point of view of acute peritoneal infection, comprises most of those which are responsible for chronic and relapsing cases. Of 24 cases of my series in which the appendix was excised in the interval between the attacks and its condition carefully noted, in nine cases the walls were greatly thickened, in seven cases there was stenosis or obliteration of the lumen with cystic dilatation of the distal end in five out of the seven, in six cases extensive adhesion with or without kinking, and two cases only was a concretion present. It is noteworthy that in most of these cases the lesion was such as, directly or indirectly to encroach upon the normal lumen of the appendix.

THE CLINICAL BASIS OF PROGNOSIS.

The uncertain and often treacherous course of appendicitis, with the insidious development of grave complications, is a matter of common knowledge. Much stress has been laid on the impossibility of ascertaining early in an attack whether resolution or suppuration will be the outcome, but on pathological grounds it is clear that from the prognostic standpoint this is not the most important point. The important questions in the first instance are, will the peritoneal infection be localised or diffuse? Is it a mild attack, or is it one of the grave forms of appendicitis with which we have to do? To determine prognostic indications we must proceed on the same lines as we do in order to ascertain diagnostic indications, and in their characters and relative significance taken as a whole we have the basis of prognosis. There is no single indication which may not mislead, but the sum of all the indications will not usually do so. These may be conveniently grouped under four headings: (1) local symptoms, (2) general symptoms, (3) local signs, and (4) the progress of the case.

1. *Local symptoms*.—(*a*) Pain is one of the most constant of symptoms, and though we may have intense pain in what develops into a mild case, and only slight pain in a case of gangrenous appendicitis which proves rapidly fatal, it is none the less true that the distribution, severity, and character of the pain are of much significance. It is, of course, common for the initial pain to be referred to the umbilical region or elsewhere rather than to the region of the appendix, but in mild cases it tends to become localised in the right iliac fossa, whereas in perforative cases the pain is usually more sudden, more severe, and more generalised. It is when pain is associated with definite collapse that it assumes its maximum importance and suggests perforation, rupture of adhesions, or rapidly spreading peritoneal infection, and we must not be misled by an interval of apparent quiescence following the onset of the acute pain. In some cases we have two distinct phases of pain—a preliminary dull aching pain or slight collicky paroxysms for a day or two and then a sudden increase in severity, the more acute pain being usually accompanied by vomiting and general disturbance. Such preliminary pain may coincide with the development of local inflammation of the appendix itself (the pre-peritoneal stage), the more severe pain with the onset of acute inflammation around the appendix (the stage of appendicular peritonitis), or again an increase of pain may be the result of spreading peritonitis, or may be attributable to the rupture of an encysted abscess. In any case a sudden increase of pain should attract anxious consideration and may be an urgent indication for immediate operation. The duration of severe pain is also of much significance, since in the majority of mild cases it soon tends to become more localised and less intense. Persistent severe pain, e.g., pain so severe as to render necessary the continuous administration of morphia or opium, generally means a severe lesion; and if the pain in addition to being persistent and severe radiates to the left iliac region or upwards, it is suggestive of spreading peritonitis. Persistent severe pain which is strictly limited to the region of the appendix is, I think, especially apt to accompany concretion. Pain which is materially increased by deep respiration is suggestive of considerable local peritonitis, and the same may be said of marked pain or difficulty on micturition. No one who has carefully compared the duration, character, and course of pain in the mild attacks of relapsing appendicitis with what

occurs in the acute perforative cases can question its significance, though it must be clearly understood that the converse of this is not necessarily true since there may be a very severe lesion without much pain, particularly with gangrene of the appendix. (*b*) Vomiting, if present, usually accompanies or follows the pain, sometimes it precedes it. It is not uncommonly absent in the mildest forms and in the majority of average cases it is an initial symptom only and ceases when the patient is kept absolutely at rest in bed and carefully dieted. If vomiting is frequent and severe, and especially if it is persistent, it is a valuable indication of a severe lesion and the same holds good of vomiting which recurs after a period of comparative repose. Of 93 cases of y series in which this symptom was carefully inquired into; 64 cases it was present at or soon after the onset and then eased, and of these 59 recurred and five died; in seven ases vomiting was persistent and severe, and of these seven ive died; and in 29 vomiting was not noted and all of them recovered. Occasionally the character of the vomit may be significant—e.g., stercoraceous or coffee-grounds vomit, both of serious import. Although as a positive indication the presence of vomiting is important its absence proves nothing—e.g., in gangrenous cases with general peritonitis it may not be present at all, but such exceptional occurrences do not detract from its general significance—a significance which I think is rather under-estimated. Constipation, not uncommonly preceded by diarrhœa, is so usual in all types that in itself it is not of any differential import, but other things being equal a natural action of the bowels and ability to expel flatus are favourable. Hiccough, especially if persistent, is unfavourable.

2. *General symptoms.*—To help us in determining how far the local lesion is affecting the organism as a whole we have two reliable guides (*a*) the temperature, pulse, and respiration, considered conjointly not separately—a point upon which I would lay very great stress; and (*b*) the aspect and general condition of the patient with especial reference to collapse, or anything approaching it, restlessness, or general distress. (*a*) Temperature. It is generally recognised that taken by itself the temperature chart in appendicitis is apt to be a fallacious guide; if, however, it be considered in conjunction with the frequency and characters of the pulse and the frequency and type of respiration we are not likely to be seriously misled. Appendicitis is typically a febrile affection, but there are at least four conditions in which the temperature may be normal or subnormal: (1) the initial collapse of acute perforative or gangrenous appendicitis; (2) fully developed septic peritonitis; (3) local suppuration, the abscess being strictly circumscribed; and (4) mild appendicitis without appreciable local peritonitis. Subject to such exceptions as these the range, type, and duration of the pyrexia have special significance. High fever of a continued type during the first two or three days generally means a severely infective lesion, but it does not tell us whether the infective process will be local or diffuse, and at times fever of this kind accompanies cases which undergo rapid resolution. A fall of temperature, if accompanied by a fall in the pulse frequency and by improvement in the general condition, is usually reassuring, but not otherwise. A secondary rise of temperature after the first few days has a very definite meaning—spreading peritonitis, suppuration, or some intercurrent complication—whilst fever persisting after eight or 10 days generally means local abscess, in which case, if allowed to continue, it will usually assume a more intermittent or remittent type. The pulse is, on the whole, of more prognostic value than the temperature provided that its characters as well as its frequency, are carefully noted, that relative rather than absolute frequency is relied on, and that a careful distinction is drawn between a persistent and a merely temporary alteration. A high pulse-rate suggests a severe lesion and in particular diffuse peritoneal infection, the more emphatically so if the pulse frequency is disproportionate to the temperature. I find that in the large majority of the less severe cases included in this series the pulse-rate was between 80 and 100; in every one in which it was persistently above 120 the attack was a severe one, and in most of them terminated in local suppuration or general peritonitis. It is true that in two or three cases when *in extremis* from general peritonitis the pulse-rate was not above 100 and in one it was below that point, but this is only what may occur in the later stages of any infective disease and does not detract from the general significance of a high pulse rate. The suggestion, which by some recent writers is treated as almost axiomatic, that a pulse-rate of 120 is an indication for operation, has much evidence to support it, but we must not forget that to wait for any such development may be to let slip the best time for operating in an acute case. Frequency and type of respiration are chiefly of importance in correcting an erroneous inference from a low temperature and pulse-rate in what may actually be a desperate condition, frequent shallow respirations of the costal type constituting under such circumstances a warning of grave peritoneal implication. (*b*) Aspect and general condition.—The importance of the pinched and anxious aspect, of restlessness, obvious distress, or collapse, are too well known to require detailed reference. Speaking generally in appendicitis such symptoms mean acute peritoneal shock or general peritonitis. The initial collapse which at times marks the onset of perforative appendicitis may be so transient that shortly afterwards the patient's general state gives no idea of the gravity of the case, but the fact of its having occurred is none the less significant. Occasionally in the most rapidly fatal cases there may be more or less persistent collapse, and the development of any such symptoms in the course of a case is naturally of the worst possible omen. Of the third group of prognostic indications it is only possible to speak very briefly.

3. *Local signs.*—The condition of the abdomen as ascertained by careful physical examination. (*a*) Impaired mobility during respiration, local or general, and distension, local or general, may go together, but in appendix cases the former is more reliable that the latter. It is quite exceptional for there to be no impairment of movement during respiration, whereas obvious distension is frequently absent throughout. Local immobility, with or without slight fulness, is the rule in cases of appendicitis with localised peritonitis. General immobility, with one important exception, points to the onset of diffuse peritonitis. The exception is diaphragmatic immobility, which appears to be due to simple reflex inhibition. This may be met with in any case in which the initial pain is very severe; it is usually transient and passes away when the pain is relieved by sedatives. With this exception we may regard the extent and degree of impairment of movement as one of the most reliable data in estimating the amount of peritoneal implication, and therefore one of our most valuable prognostic indications. (*b*) Local tenderness.—The area of local tenderness affords some guidance as to the extent of the local inflammation, provided always that the patient's sensibility is not dulled by opium or by collapse. When there is little or no circumjacent peritonitis the tenderness may be strictly limited to the region of the appendix, e.g., in chronic appendicitis and in the early stages of acute appendicitis. In most cases of perityphlitis with considerable local peritonitis there is a considerable area of tenderness in the right iliac region with its maximum intensity over the appendix, whilst in the more severe forms with widespread peritonitis we find marked tenderness in the left iliac fossa and possibly over the whole abdomen, and in some of the gravest cases there is some general abdominal tenderness but no special local tenderness in the appendix region. As one other instance, persistent or increasing local tenderness may be almost the only sign of localised suppuration within or near the appendix—a condition the prognostic significance of which is obvious. (*c*) Muscular rigidity corresponds more or less closely with cutaneous hyperæsthesia and tenderness, so that in relation to prognosis the two would be noted together. (*d*) Local tumour or deep-seated resistance is very common, but as it is frequently absent in severe cases with diffuse peritonitis and often not discernible at first its prognostic value is very limited. It is important to bear in mind, contrary to what was believed in the old days when perityphlitis was held to be due to fæcal accumulation, that the absence of any tumour or swelling in the right iliac fossa not only does not contraindicate the existence of perityphlitis, but may be of serious prognostic significance in relation to it as being suggestive of the absence of the local peritonitic barrier, which so often shuts off the infected area from the general peritoneum. On the whole we are justified in saying that given appendicitis a definite local tumour is reassuring. What has been said as to the significance of local tumour would, with slight modification, apply to dulness on percussion.

4. *Progress of the case.*—In many instances when first seen the condition has so far developed as to provide definite data for prognosis; if, however, the case is seen early this

may not be so. Under such circumstances the development of events in the ensuing 24 hours, 36 hours, or 48 hours may furnish the needed indications for prognosis and treatment. In the milder cases symptoms will tend to recede or at least to become more localised. On the other hand, if the affection be of a severe type the symptoms will persist or become intensified, though sometimes only after a treacherous remission which may very readily mislead.

II.—PROGNOSIS AS TO RECURRENCE.

Statistics vary as to the frequency of recurrence: some authorities place it as high as 47 per cent., others at below 30 per cent.; in my series it was 31 per cent. It may, then, be expected in about one third of the cases. We also know that the tendency to recurrence usually manifests itself within two years, and most commonly within one year, of the first attack. Besides such general facts to guide us the following clinical features will aid in forming an opinion as to the likelihood of recurrence in any particular case. 1. The nature of the first attack.—If there were local suppuration the probability of recurrence is relatively slight; on the other hand, a mild first attack is frequently followed by recurrence. 2. Convalescence from the first attack.—If the condition clear up but slowly and local pain, local tenderness, or slight swelling persist for some time the probability of relapse sooner or later is very great. 3. Condition in the interval between attacks.—If there is occasional pain or discomfort with irregularity of the bowels and definite local tenderness or resistance a chronic appendicitis probably exists. The palpation of the enlarged and thickened appendix will render the latter diagnosis certain, which means a chronic tendency to relapse so long as the appendix is allowed to remain there.

Upper Berkeley street, W.

A NEW AND MORE PERMANENT METHOD OF MOUNTING AMYLOID SECTIONS, STAINED WITH IODINE.

BY ALAN B. GREEN, M.A., M.B., B.C. CANTAB.

THE following process of mounting amyloid sections stained with iodine gives more permanent results than any other method which I have met with. Some sections stained and mounted in this way have, after seven weeks, apparently not deteriorated in the least; no change can be distinguished. Whether the method is permanent in its results time alone can show, but I hope that this will prove to be the case. The following solutions are required:—(*a*) Weigert's iodine. (*b*) Pure liquid paraffin (30 cubic centimetres) and iodine crystals (one gramme). The purest liquid paraffin used for lamps is the best for this purpose. (*c*) Xylol (30 cubic centimetres) and iodine crystals (one gramme).

First place on a coverslip a small quantity of pure white vaseline ready for immediate use for mounting the stained section. Float the section from water on to a glass slide and drain and blot away as much water as possible.

From a drop-bottle pour a few drops of solution (*a*) on the section until it is sufficiently deeply stained. Then drain away excess of solution and from a second drop-bottle pour a fine stream of solution (*b*) over the section. This dehydrates the section without removing any iodine from it. Now drain away excess of solution (*b*) and remove the last traces of it by pouring over the section from a third drop-bottle a stream of solution (*c*). Finally, drain away excess and blot quickly to remove the remaining solution (*c*). Then at once place the coverslip with the vaseline on it in position over the section. The coverslip may afterwards be ringed.

Pathological Laboratory, Cambridge.

SHEPTON MALLET DISTRICT HOSPITAL.—The annual meeting of this institution was held on Jan. 27th under the presidency of Sir R. H. Paget. The medical report showed that 132 in-patients had been treated, against 124 in 1898. There were also 116 out-patients and 55 casualties treated, both being in excess of the preceding year. The financial statement showed an increase under all heads and the balance was satisfactory.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A SUCCESSFUL CASE OF ENTERECTOMY FOR GANGRENOUS HERNIA.

BY ARTHUR H. BURGESS, M.B., M.Sc. VICT., F.R.C.S. ENG.,

RESIDENT SURGICAL OFFICER, MANCHESTER ROYAL INFIRMARY.

A BOY, aged 15 years, was admitted to the Manchester Royal Infirmary on Dec. 13th, 1899, with a strangulated inguinal hernia on the right side, the symptoms of strangulation having existed for four days. Taxis had been attempted by a medical man but had failed. On admission his general condition was found to be extremely grave, all the chief signs of acute intestinal obstruction being present. There was a small tense swelling in the right inguinal region without any impulse on coughing, the skin over which presented a dusky red appearance and pitted slightly on pressure. Under chloroform the sac was opened and about one ounce of a feculent fluid escaped. A knuckle of small intestine about two and a half inches in length was found tightly strangulated and in a gangrenous condition, a perforation of the size of a threepenny-piece at the summit of the loop having allowed the intestinal contents to escape into the sac. On dividing the constriction at the neck of the sac and drawing down the coil a second but smaller perforation was found in the entering limb of the loop opposite the constriction. The wound was enlarged upwards, the coil was drawn out of the abdomen as far as possible, clamps were applied on either side, and about four inches of intestine, including the gangrenous piece, were incised along with a V shaped portion of the mesentery. The divided ends of the gut were then united by direct suture, the mucous membrane being first joined by a continuous suture of the finest silk, then the sero-muscular coats by a continuous Lembert's suture, lastly the divided mesentery also by a continuous suture. The gut was reduced, the sac was isolated and ligatured near its neck and cut away, a radical cure being afterwards rapidly performed by Mr. Joseph Collier's method. The wound was closed except at the lower angle in which a gauze drain was inserted. The patient made an uninterrupted recovery without an unfavourable symptom, the temperature of 99° F. on the second night being the highest recorded. The bowels acted slightly two hours after operation, again six hours later, and again 13 hours later. Only warm water was allowed for 36 hours, then warm tea, and milk and soda-water. Benger's food was given on the twelfth day and then a gradual return to ordinary diet was permitted. The wound healed without suppuration and all the sutures were removed on the fourteenth day. The patient was allowed up at the end of three weeks, and was sent to a convalescent home at the end of five weeks. For permission to report the foregoing case I am indebted to Mr. F. A. Southam for whom I was acting at the time.

Bowdon, Cheshire.

A CASE OF COMPLETE INVERTIO AND PROLAPSUS UTERI.

BY F. L. POCHIN, M.B., C.M. EDIN.

ON the evening of Dec. 27th, 1899, I was called to a primipara, aged 20 years. The midwife who sent for me stated that one child was born but that there was another child, dead, which she was unable to deliver. On examining the patient I found a firm fleshy pyriform mass of a dark claret colour and of about the size of the fœtal head projecting from the vulva. To the exact apex of this mass about one-fifth of the maternal surface of the placenta was still adherent. On digital examination per vaginam the finger passed at once into a cul-de-sac formed by the stretched and inverted vaginal walls. No uterus could be felt through the abdominal wall. The tumour did not harden on taxis. Despite the fact that hæmorrhage had not been excessive the patient was very much collapsed. The face was cadaverous, the lips were bloodless, the pulse was rapid and hardly perceptible, the breathing was quick and shallow, and the extremities were cold. Having detached the placenta and bathed the uterus well with hot boiled water I returned the mass without any difficulty by squeezing it well with both hands and at the same time exerting steady upward pressure in the pelvic axis, following up the uterus with my closed fist until its normal position was reached and the inversion was quite rectified. I then administered sterilised ergot and brandy subcutaneously and slowly injected a quart of hot saline solution per rectum. The patient was also surrounded with hot bottles. Under this treatment her condition quickly improved, the pulse became markedly stronger, perspiration broke out on the skin, and the extremities became warm, while the patient expressed her relief. The puerperium was comparatively uneventful. The lochia became slightly offensive and the temperature rose to 101° F. on the second day, but an intra-uterine injection of one-half per cent. of lysol solution put all right again.

This accident is an extremely rare one. It only occurred once in 190,800 deliveries at the Rotunda Hospital, Dublin (Playfair). In the clinic of Braun and Spaeth no complete case was observed in 250,000 births (Lusk). The case mortality is about 42 per cent. (Crosse). The condition has been ascribed to traction on the cord either by the midwife or as a result of the funis being twisted round the child's neck. Insertion of the placenta exactly at the fundus is considered to predispose to the accident. In this case the patient had been intensely anæmic for a long time before delivery, there had been "some trouble with the afterbirth," and the midwife had "pulled the cord a little." The cord was not twisted round the child's neck.

ST. MARY'S HOSPITAL FOR SICK CHILDREN, PLAISTOW, E.

A CASE OF DIPHTHERIA OF THE VULVA.

(Under the care of Dr. E. E. WARE.)

THE diagnosis of diphtheria is always much facilitated by the identification of the bacillus and when also paralysis supervenes the diagnosis is certain. It is a little remarkable in this case that although the diphtheritic patch was situated on the vulva the muscles first paralysed were those of the palate, but the same combination has been noticed before. The explanation is probably to be found in the fact that even slight paresis of the palate muscles would be noticeable long before the same amount of weakness in the leg muscles would become evident. For a similar reason strabismus is often a very early sign of diphtheria. The local antiseptic treatment of diphtheritic patches on external parts of the body is always advisable, though when the palate is affected the harm which the child suffers from fear and struggling probably outweighs the benefit which might result from the antiseptics. The antiseptic employed, however, should not be very strong, otherwise the damage to the tissues may weaken their power of resistance. For the notes of the case we are indebted to Mr. W. W. Farnfield, late resident medical officer.

A girl, aged four years, was admitted into St. Mary's Hospital for Sick Children, Plaistow, E., on Jan. 26th, 1899, with the following symptoms. During the five days preceding admission the patient had suffered great pain on passing urine, the act sometimes taking a quarter of an hour owing to frequent involuntary stoppages. She had not seemed to be as well as usual, she had lost her appetite and had been listless. She had had no previous illness. The patient was a well-nourished child. The temperature on admission was 100° F., the pulse was 120, and the respirations were 28. On examination of the vulva there was seen to be undue redness of the parts which were evidently very tender. The urine was acid; its specific gravity was 1015 and it contained no albumin, pus, or blood. The act of micturition was very painful, the patient screaming while passing urine, but the pain did not continue after the act.

On Jan. 29th the A.C.E. mixture was administered and the bladder was examined both with the sound and bimanually, the forefinger of the right hand in the rectum and the left hand on the abdomen, but the result was negative. It was then noticed that two circular white patches were present on the vulva, one on the vestibule and the other on the right nympha, each being about one-eighth of an inch in diameter; they were considered to resemble diphtheritic membrane, and accordingly a blood-serum tube was inoculated. There was no affection of the throat or eyes. As typical Klebs-Löffler bacilli in pure culture were present on the blood-serum the patient on Jan. 30th was injected with 2000 units of anti-diphtheritic serum. On Feb. 1st the membrane had disappeared and the redness of the vulva was less marked; there was very little pain on micturition. The temperature was 98° and the pulse was 120. On the 8th micturition was quite painless and the vulva was perfectly normal in appearance, but the patient was still very listless. On the 19th the temperature rose to 102·8° and the pulse was 150, and the child vomited. A hypodermic injection of three minims of liquor strychninæ hydrochloridi was given. Nasal regurgitation of fluids on drinking was noticed. By the 21st her general condition had improved. The temperature was 99° and the pulse was 120. The nasal regurgitation occurred only occasionally. From this time recovery was uninterrupted and on Feb. 25th fluid no longer regurgitated through the nose. On March 11th the patient was sent to the convalescent home at Southend.

Remarks by MR. FARNFIELD.—There is no doubt that this was a case of true diphtheria of the vulva, for even had there been no bacteriological examination the onset of paralysis of the soft palate may be taken as sufficient proof. The symptoms were misleading and pointed to the probability of stone in the bladder, this being the commonest cause of severe pain on micturition in a child, and it was thought that the local redness was due to handling in consequence of reflex irritation. I am indebted to Dr. Ware for permission to publish this case.

SUSSEX COUNTY HOSPITAL.

A CASE OF INTERSCAPULO-THORACIC AMPUTATION.

(Under the care of Mr. T. J. VERRALL.)

AMPUTATION of the whole upper extremity with removal of the scapula and part of the clavicle (or as it is often called "interscapulo-thoracic amputation") has been specially described by Paul Berger.[1] The chief dangers of the operation are hæmorrhage and shock.[2] Hæmorrhage is in great part controlled by the preliminary ligature of the subclavian artery and vein, but this does not affect the hæmorrhage from the supra-scapular and posterior scapular vessels. This is the most thorough operation which can be performed for malignant disease of the upper part of the humerus and recurrence does not occur in a very fair proportion of the
cases. Of 43 cases in which interscapulo-thoracic amputa
tion was performed 34 patients recovered from the opera
tion; in 10 of these the ultimate result was uncertain. I
14 of the remainder recurrence occurred; in 11 of the 1
the recurrence appeared within 12 months of the operation

A married woman, aged 39 years, was admitted into t
Sussex County Hospital on March 21st, 1898. Five mon
previously she noticed that the upper part of the left a
would show swelling which persisted for a day or two
then disappeared. There was always some pain in the s
especially on movement, which was not so free as was nat
For two months work had been impossible, but it was
three weeks since the swelling took a definite shape

[2] Jacobson's Operations of Surgery, second edition, p. 157

became persistent. Though she ate well she had grown much thinner of late. There was a fusiform swelling of the upper third of the humerus spreading into the axilla and back on to the scapula. All the shoulder muscles were wasted and she could only move the arm about three inches from her side. The pain was severe, especially at night. The skin over the humerus was moveable, but there were several large veins. There were no enlarged glands to be felt. Before the time of the operation it became evident that the bone had snapped high up near the joint.

On April 1st the upper extremity was removed according to the plan of Paul Berger. Previously to commencing the real operation an incision was made into the tumour. This, which showed an extensive malignant growth, was unnecessary for diagnosis, but the patient had been promised that the arm should not be sacrificed till the examination of the tumour had been made. As much blood was lost from this incision as from the rest of the operation. It was also to be deprecated on account of the risk of infecting sound parts. After removing the middle third of the clavicle and cutting through the subclavius no difficulty was found in securing first the subclavian artery and then the vein, each between two ligatures. Skin flaps, pectoro-axillary and cervico-scapular, were made, the arteries were caught as they were divided, and there was no bleeding of consequence till the division of muscles attached to the posterior border of the scapula. The wound was drained with one tube. The operation was very well borne. The long wound healed by primary union, with the exception of one and a half inches at the centre, where there was a superficial slough of the flap edge. This part was not quite healed when the patient left the hospital on the seventeenth day. She, however, was walking about and feeling well. Examination of the limb showed that the whole upper part of the humerus was affected and apparently the shoulder joint, although the scapula was healthy so far as naked-eye evidence went. The growth under the microscope was seen to be sarcoma containing abundant small round cells and some spindle cells. No large myeloid cells were discovered.

The patient has been under observation up to the present time (Feb. 1st). There is as yet no sign of recurrence. She complained, especially at first, of pain in the site of the cut ends of the brachial plexus; exalgine and quinine have controlled this. Her general health is good and she has recovered weight.

Remarks by Mr. VERRALL.—In a contribution to the *Annals of Surgery* this month Russell Fowler insists that this operation should be done in all cases of malignant disease of the humerus, however located, whether in the upper extremity, shaft, or lower extremity of the bone. In my case I selected it partly from the grave suspicion that the scapula was diseased, also for the fear lest with a less operation it would be impossible to get sufficient flaps wide of the tumour. Doubtless the control of hæmorrhage is the first point to consider. If the tumour actually encroach on the subclavian region I can imagine great difficulty in securing the main vessels; but here there would be but little prospect of permanent cure, even if the immediate result was good. In my case the vessels were found and ligatured without delay and no large amount of blood was lost, although the cut into the tumour oozed until the limb was removed. The extreme rapidity of recovery in this case was very striking, so also was the immediate improvement in the general condition of the patient. With regard to the question of recurrence I have delayed reporting till a considerable time had elapsed and I could fairly hope the cure was permanent. Although I cannot feel sure, even after 22 months, that this is effected, I may fairly hope it is. Of the 72 cases tabulated by Fowler in the paper above alluded to eight died from the operation, others recurred at various dates, in others no further report was given, and only 14 were well at the time when reported, as much as one year or more after the operation.

ROCHDALE INFIRMARY.

A CASE OF INTESTINAL OBSTRUCTION ARISING FROM MECKEL'S DIVERTICULUM.

(Under the care of Mr. R. B. SELLERS.)

THE extremity of a Meckel's diverticulum may remain adherent to the umbilicus or it may form a fresh adhesion elsewhere, especially to the mesentery. In either case it may give rise to intestinal obstruction, and the same result may also be due to the diverticulum even when it is unattached. Considering that this vestige is found in 2 per cent. of all the bodies examined[1] it is somewhat strange that it does not give rise to symptoms more frequently. The symptoms of obstruction are usually rather acute, and the diagnosis can only be made after a laparotomy. For the notes of the case we are indebted to Dr. T. Hillhouse Livingstone, house surgeon.

A man, aged 32 years, was admitted into the Rochdale Infirmary in a more or less collapsed condition. There was a history of five days' duration of abdominal pain chiefly referred to the epigastric region, together with nausea, vomiting, and intense thirst. The bowels were obstinately constipated and glycerine enemata were ineffectual and had been for two days before admission, and at the same time no flatus had been passed. The patient had not been feeling well for some weeks beforehand and apparently the more acute symptoms which supervened were an exacerbation of the old complaint. The pulse was wiry in character and 120 to the minute; the temperature shortly after admission was 101·4° F. On account of the collapsed condition very few subjective symptoms could be elicited, but it appears that colic was the first symptom, followed shortly afterwards by vomiting and later by distension of the abdomen. Shortly after admission the vomiting became fæcal in character and the man was covered with a cold clammy sweat. His tongue was very dirty with a white fur at its edges and a dirty brown strip down its centre. No intestinal peristalsis was visible. The intense thirst was relieved by giving the patient ice to suck. No fluid could be made out in the peritoneal cavity and the rectal examination revealed nothing; neither was there any evidence of external hernia. In case of intussusception being present a long rubber tube was passed up the rectum and warm boric lotion was injected, but no improvement resulted. Everything pointed to operative treatment to relieve the obstruction.

The abdomen was accordingly opened in the linea alba by an incision reaching from the umbilicus to three inches above the pubes, the bladder having previously been emptied by a catheter. The peritoneum was opened and a band was found adherent to the umbilicus. On closer examination it was found to have a lumen with a closed extremity at the umbilicus; the other end was attached to the small intestine and a coil of small intestine was tied down and strangled by the diverticulum, the serous coat being ulcerated. It was impossible to separate the apex of the diverticulum from the umbilicus, and therefore it was divided after a ligature had been applied to the distal end. The proximal end was secured by forceps and was afterwards excised near to the mother gut by raising a cuff of peritoneal and muscular coats and ligaturing the mucous coat, after which the two outer layers were inverted by means of a Lembert's suture of fine catgut. The abdomen was stitched up and the patient was put to bed with the foot of the bed raised and plenty of hot bottles. Unfortunately, the patient had not been admitted soon enough; fæcal vomiting came on again and he became delirious and in spite of stimulants he died 12 hours after the operation.

Necropsy.—Permission to make a post-mortem examination was obtained and on opening the abdominal cavity peritonitis was seen to be almost universal. There was no perforation and the Lembert's sutures were efficient. The diverticulum branched off from the small intestine about three feet above the ileo-cæcal valve and must have been about four or five inches long. The appendix was found to be abnormally long, so long that it reached across to the left iliac fossa and was at first mistaken for a second diverticulum.

Remarks by Dr. LIVINGSTONE.—In this case the malformation caused by the non-obliteration of the omphalo-mesenteric duct running between the blastodermic vesicle and the intestine in fœtal life coincided in its position with the position recorded in other cases, for it was a short distance above the ileo-cæcal valve at right angles to the ileum. Its situation in this case—opposite the mesenteric attachment—is, I think, also fairly constant. From the evidence at the post-mortem examination death was attributed to peritonitis which had existed before admission.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

e Part played by Insects in the Spread of Malaria.—Experimental Production of Amyloid Disease in Animals.—Neutralisation of Cobra Venom by its Antitoxin.—Cortical Changes in Acute Chorea.—Nervous Disturbances of Respiration, Mastication, and Deglutition and the Movements of the Larynx.

A MEETING of this society was held on Feb. 6th, in the Pathological Laboratory of University College, Mr. A. PEARCE GOULD, Vice-President, being in the chair.

Mr. A. PEARCE GOULD referred in suitable terms to the recent death of Dr. Charlewood Turner. He also announced that the council had appointed himself, as the senior surgical vice-president, to act as president during the absence of Mr. Watson Cheyne in South Africa.

Dr. GEORGE H. T. NUTTALL demonstrated a number of Microscopic Lantern-projections which had been lent him by Dr. Ross and other observers illustrating recent investigations into the Part played by Insects in the Spread of Infective Diseases, especially Malaria. The specimens illustrated in a very graphic manner the gradual growth of the parasite within the body of the mosquito, how the capsulated organism burst, and the sporozoites became liberated into the body-cavity of the mosquito. These then became deposited in the salivary glands of the insect, by which means they became imported into a fresh host, there o undergo a development like their parents. These specimens referred to the proteosoma, which was the malarial parasite of birds. Specimens of the filaria perstans were also exhibited. By means of his observations on this insect Dr. P. Manson had been lead to conclude that the mosquito was the chief agent in the spread of malaria. Specimens showing the parasite of quartan ague and the tertian parasite in the stomach of the anopheles were also exhibited.

Mr. STRANGEWAYS PIGG (for Dr. Alan B. Green) communicated the results of an inquiry into the Experimental Production of Amyloid Disease in Animals. The animals used were rabbits and chickens. Healthy rabbits and chickens were used, and the micro-organism employed was staphylococcus pyogenes aureus. One cubic centimetre of a broth culture (24 hours' incubation) was injected either subcutaneously, intravenously, or peritoneally in rabbits and into the pectoral muscle of the fowls. The dose was gradually increased as toleration was established. Only two out of the 20 rabbits experimented on ultimately survived. Of the two fowls one succumbed on the fifteenth day after the first injection. Some of the rabbits lived for three, four, and five months. The tissues were hardened with a 5 per cent. formalin solution, as alcohol and other hardening reagents undoubtedly affected the reaction for amyloid materials. In the rabbits no definite amylaceous changes could be identified, though in some of the tissues a pinkish colouration was obtained. Sections of the organs of the fowl were stained distinctly pink with methyl violet and gave the characteristic mahogany brown stain with iodine. Sections of the organs of the rabbits showed what Dr. Green believed to be probably a hyaline degenerative change. They gave a pink colour with methyl violet, but this faded when mounted in Farrant's medium, glycerine, or salt solution and the whole section became blue. The rabbit, sections of which were under the microscope, had lived several months under the injections, during which time it lost weight. The hen, sections of which were shown, succumbed on the fifteenth day after the first injection. During this time it had seven injections and went down slightly in weight. Post mortem Dr. Green discovered no signs of amyloid disease macroscopically in any animal. Fragments of the spleen of the hen kept for six weeks in 5 per cent. formalin showed rather less vivid pink colouration when stained with methyl violet than those fragments hardened for only 24 hours. Frozen sections were cut to avoid passing the tissues through a series of alcohols for the same reason. He was preparing, however, some paraffin sections. In every case sections of the rabbits' organs showed only what he thought to be most probably hyaline degeneration changes. Generally the hyaline material stained bright pink with methyl violet, but when mounted in Farrant's solution, glycerine, or salt solution the pink faded entirely in a few days or hours, leaving the whole of the section blue. The pink also faded the section was placed in a 1 per cent. hydrochloric acid bath. The only way he had been able to keep the colour permanently in the sections was after dehydrating sections with pure liquid paraffin such as used for lamps, washing in xylol, and mounting in vaseline. When stained with iodine these sections showed the degenerated parts only slightly darker than the normal parts. In the sections of organs of the hen he had obtained entirely different results from those obtained in the rabbit. The appearance in the case of the hen was that of true amyloid degeneration. Stained with methyl violet the red colour did not fade in Farrant's solution; or glycerine sections might be stained deeply with methyl violet, or excess of stain removed in a 1 per cent. HCl bath without causing the pink colour to fade. Stained with iodine the degenerated parts took a deep mahogany brown stain. The specimens, which were exhibited in an adjacent room, he need not describe.

Dr. W. MYERS gave an account of his investigations into the Neutralisation of Cobra Venom by its Antitoxin, made with a view of throwing some light on the nature and composition of the venom of the cobra. The venom contained two distinct kinds of toxin, one a hæmolytic and the other a nerve toxin. If the venom of the cobra were gradually heated the hæmolytic toxin was destroyed before the nerve toxin. In a concentrated form the cobra venom was constant and retained its strength, but in a dilute form (say, 1 per cent.) its toxic power diminished by keeping. Dr. Myers's investigations had been made with Calmette's antitoxin and to explain the results obtained it was necessary to assume the existence of a "toxoid" substance, and in general terms hypotheses similar to those enunciated by Ehrlich explained the results obtained.

Dr. BERTRAM ABRAHAMS read a paper on the Cortical Changes in Acute Chorea. He showed a series of lantern slides and microscopic specimens illustrating the changes in the parietal cortex of a woman, aged 28 years, who died on the thirty-seventh day from an attack of chorea gravidarum. The choreic movements were at first confined to the left side, the right being unaffected till shortly before death. There was fairly constant but moderate pyrexia throughout the illness. The cortex of the left hemisphere was very little altered, there being only a moderate exudation of leucocytes and a slight increase in size of the peri-neuronal lymph spaces. The condition was evidently a very early stage of that seen on the right side. Here Meynert's columns were obliterated by a profuse exudation of small cells, which appropriate staining proved to be uninuclear leucocytes. These were shown in the act of exuding from the smaller blood-vessels. The peri-vascular and peri-neuronal lymph-spaces were much dilated and the cortex generally was distinctly œdematous. The pyramidal cells were seen to be considerably altered in appearance. They were frequently bulged laterally and many of them had their processes broken off. The nuclei were often swollen and pale but the nucleoli stained with unusual distinctness. The Nissl bodies, on the other hand, were seldom well-marked and the pigment was much diminished in amount. In the enlarged spaces around the cells a large number of uninuclear leucocytes were shown to have accumulated. Th changes were on the whole similar, though in less degree, to those described by Dr. F. W. Mott in cases of status epilepticus and, as in them, the alterations in the cells appeared to depend upon modifications in the chemical condition of their lymph environment. It was obvious, moreover, that their nature and extent were perfectly compatible with complete recovery. With regard to the general question of the pathology o chorea the appearances tended to support the view that th inflammatory changes in the cortex were not due to loca causes but arose secondarily to toxic alterations in th blood.

Mr. W. G. SPENCER and Dr. RISIEN RUSSELL demonstrat some experiments bearing on the Nervous Disturbances Respiration, Mastication, and Deglutition and the Mo ments of the Larynx.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Feb. 1 President, Dr. W. H. LAMB, being in the chair.

Mr. D'ARCY POWER showed a case of Inward Displ of the Lower Epiphysis of the Humerus and illustrated it with skiagrams. The patient was a girl, aged six years, who fell upon her left arm in September, 1899. It was impossible to obtain details of the accident, which happened in Cornwall, but the arm had been kept in splints for six weeks. She was admitted to the Victoria Hospital for Children on Jan. 1st, 1900, on account of a deformity of the elbow. The arm was in a state of cubitus varus—that is to say, the long axis was directed inwards at the elbow, but there was neither shortening nor wasting. The movements of flexion, extension, pronation, and supination were unaffected, and the patient only complained of a little pain over the projecting external condyle. Mr. D'Arcy Power had hesitated, therefore, to perform any operation, thinking that if he did so the last state of the arm might possibly be much worse than the first. The skiagram showed that it would be quite easy to chisel away the projecting angle of the shaft of the humerus. He thought, however, that it would be better to do this when the developmental processes at the elbow were completed. Mr. D'Arcy Power pointed out that the case belonged to a very obscure class of injuries to the elbow the exact nature of which is only now becoming known by the application of the Roentgen rays. The skiagram showed that the separation of the lower epiphysis of the humerus had been subperiosteal and had resulted in a shifting of the whole epiphysis towards the inner side. The displacement had led to the external condyle of the humerus losing its cartilaginous covering, whilst the cavity of the olecranon had its long axis oblique instead of vertical. The epiphysis appeared to be fixed in its new position by ossification of the periosteum which had probably been injured at the time of the accident and by an increased width of the internal condyle which served to support the epiphysis in its new position.

Mr. **Jackson Clarke** demonstrated the method which he employed for supporting the spine in caries of the cervical and upper dorsal regions, as applied to a patient, aged eight years, in whom the disease was situated about the fifth and sixth dorsal vertebræ. The patient had been treated as an out-patient for over a year and she had gained in general health and the local spinal trouble had improved greatly in that time. The support used was a form of Chance's splint furnished with an occipital horseshoe-shaped piece to which was added a chin-strap. The principle of antero-posterior support in spinal cases was approved by the late Sir John Erichsen in the shape of Taylor's splint introduced in 1870. Mr. Clarke found that Chance's splint, which was introduced in 1850, was simpler and in some ways better than the other. After a long and careful comparison with the various forms of corsets he had no hesitation in deciding in favour of the method of antero-posterior support.—In answer to Mr. **Douglas Drew** Mr. **Clarke** said that he based his judgment upon extensive clinical experience.

Dr. **A. Whitfield** showed a boy, aged 16 years, suffering from Acne Vulgaris combined with marked Seborrhœic Eczema. The patient was in the grocery trade and worked very late hours in hot rooms, but he stated that his general health had never suffered in any way. For about three years he had suffered from acne of the face, and for about a year he had noticed that his head had become very scurfy and that red spots occasionally came out on his chest. During the last month the condition of the head and chest had become much more marked and red spots had come out on his back and face. On examination Dr. Whitfield was struck by the presence of enormous numbers of comedones on the face, especially on the forehead and cheeks. Most of these were large and prominent, but few only were much inflamed, pustulation being present only in slight degree The skin of the face was noticeably greasy, a condition which might partly be accounted for by insufficient washing, but was undoubtedly more than a mere accumulation. The whole of the scalp was covered with a very thick greasy scale, which extended downwards in a gyrate manner on to the left side of the forehead. Where the rash reached the forehead it was seen to be of a florid red colour with very defined outline and covered with a yellowish scale On the chest and back a considerable number of comedones could be seen without any inflammatory areola around them, and in addition to these there was a number of discoid patches varying in size from that of a small lentil to that of a sixpenny-piece. These patches could be traced from single follicular papules, and when they had extended centrifugally they became bright red hyperæmic spots without infiltration, but covered with an adherent and rather greasy scale. The condition thus strongly simulated psoriasis at the edge of the hairy margin of the scalp, and on the chest and back. There were, however, no other lesions on the elbows or knees, and the facts that the disease was associated with a general, seborrhœic condition of the skin and that these psoriasis-like spots took origin from small follicular papules would seem to justify the diagnosis of seborrhœic eczema. Dr. Whitfield alluded to the fact that some observers were inclined to identify seborrhœic eczema with psoriasis, as the same disease, and said that he himself believed them to be distinct, and that, while admitting that the differential diagnosis was occasionally very difficult he saw no reason for therefore believing them to be identical. He had ordered an ointment containing 2 per cent. of salicylic acid and 3 per cent. of sulphur to be used and if the disease did not yield to this he should add some oil of cade to the ointment.

Dr. **Herbert Tilley** showed two cases of Chronic Frontal Sinus Empyema in which the radical external operation had been performed. In both cases the disease was bilateral. In the case of the female patient he had operated on both sides; in that of the male patient he had as yet only operated on one side. The results were extremely gratifying. In both cases relief was sought for nasal obstruction and profuse purulent nasal discharge. In neither case had headache been a prominent symptom. In each instance the maxillary antra contained pus. Dr. Tilley laid great stress on the importance of removing intra-nasal pathological conditions before proceeding to the external operation. His usual line of treatment was to remove the nasal polypi or chronic inflammatory products from the region of the middle meatus and also in all cases the anterior half of the middle turbinate bone, which was nearly always diseased in chronic cases and formed an obstruction to free discharge from the frontal sinus. If the antrum contained pus it was drained by the alveolar method. When the nose, and more especially the region of the middle meatus and anterior ethmoidal cells, was healthy then the external operation might be undertaken with every prospect of success. This consisted in making an incision in the inner third of the line of the eyebrow, terminating just above the internal palpebral ligament. The anterior wall of the sinus was removed entirely if the sinus was only of a moderate size, otherwise only a portion of it. The diseased mucous membrane was then thoroughly curetted and a large opening made into the nose (an enlargement of the normal fronto-nasal canal); this should be sufficient to admit the tip of the little finger passed up from the nose. A drainage-tube was inserted in cases where the sinus had not been obliterated. The wound was closed at the end of the operation by one or two stitches and the resulting scar was hardly noticeable. In the patients exhibited there was complete relief from all symptoms.—In reply to Mr. **D'Arcy Power**, Dr. **Tilley** said that the danger of operative interference in this region was much minimised by a careful preliminary study of and acquaintance with the anatomy of parts involved, and as the frontal sinus did not develop till the seventh year of age and remained small till after puberty, such treatment would be very rarely called for in young people.

Dr. **William Ewart** showed a case of Tachypnœa in association with Upward Dilatation of the Stomach. The patient, a female, aged 18 years, had suffered from infantile bronchitis and from habitual cough and for four years from shortness of breath on exertion. She had recently been laid up in bed for three weeks with rapid breathing, orthopnœa, oppression across the sternum, and discomfort at the left thoracic base. On admission the suspicion that the case might be one of hysterical tachypnœa was not confirmed by the aspect or history. Scattered wheezes were heard in the chest and the dyspnœa was genuine. The tachypnœa, which was not complicated with any increase of the pulse-rate or of the depth of the respirations, suggested the likelihood of upward dilatation of the stomach as a cause. This was also rendered probable by the distension and oppression at the lower sternum and the regurgitation of bitter-tasting food after meals. On examination the stomach was found to be dilated upwards as far as the level of the fourth costal cartilage, rising above the level of the cardiac which was in the normal situation. The tympanitic note encroached upon part of the cardiac dulness and replaced the dulness of the left lobe of the liver. The chest did not present the usual signs of emphysema and subsequently gave ample respiratory movements as the patient recovered under appropriate gastric treatment. The tachypnœa was never extreme (53 per minute). On the day when the tachypnœa and respiratory distress were relieved a further examination showed that the upper boundary of the gastric resonance had returned to the normal level. Additional features of interest in the case were the liability to pseudo-rheumatic pains in the joints, the decayed condition of several of the teeth, and the presence of a tape-worm which had been allowed to remain without treatment for the last four years —In discussing this case Mr. SEFTON SEWILL said that a point of interest was raised by Dr. Ewart's paper inasmuch as Professor Arkövy had some time ago described a bacillus which was constantly found in the pus of abscesses of dental origin, especially in those of a chronic nature. This was named "bacillus gangrenæ pulpæ" and Dr. William Hunter in a paper read before the Odontological Society of Great Britain had ascribed to its presence in the stomach several troublesome affections of that organ. The point was the importance of bringing the mouth into a thoroughly healthy state in all cases of disease of the stomach.

Dr. ALFRED EDDOWES showed: 1. A rapidly recovering case of Alopecia Areata The patient, a male, aged 16 years, had been treated by several medical men but the disease had become nearly general and had been looked upon as almost hopeless. Thyroid extract was administered and lysol solution was applied locally with the result that the hair was rapidly returning to its normal colour and the patient was growing fast and improving in every way. Dr. Eddowes believed that the case was essentially leucodermia of hairy parts. He said that too many cases of alopecia occurred with leucodermia for the association to be merely accidental. He looked upon alopecia as a condition produced by several causes and not as a distinct disease. He had known leucodermia to be recovered from. He now had much greater success in treating alopecia than formerly. 2. Coccogenic Sycosis, which had commenced on the upper lip, apparently from infection due to discharge from the nose. The patient had had sore eyes for many years. Dr. Eddowes thought that the discharge from the eyes had infected the nose and thence the lip, and that it would be almost useless to treat the sycosis without treating the eyes. He had seen three cases of the kind in one afternoon at the hospital. He applied yellow oxide of mercury ointment to the eyes, with a dressing and bandage at night. To smear ointment on the lids in such a case was almost useless, as grease ran off wet eyelids like water off a duck's back. 3. Lupus Vulgaris in a condition like Scrofulodermia 4. A woman suffering from Xerodermia of the Hands and Ichthyosis of the Legs, improving in health and condition of skin under thyroid extract.

Mr. DOUGLAS DREW showed a case of Large Fibro-Adenoma of the Breast.

The various cases were discussed by Mr. D'ARCY POWER, Mr. J. JACKSON CLARKE, Mr. DOUGLAS DREW, Mr. EDMUND ROUGHTON, Mr. SEFTON SEWILL, Dr. ARTHUR WHITFIELD, Dr. EDDOWES, Dr. HERBERT TILLEY, and the PRESIDENT.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

The Notification of Phthisis —The Treatment of Gonorrhœal Arthritis —Cases and Specimens

A MEETING of this society was held on Feb 2nd, Dr. GORDON BLACK, Vice-President, being in the chair.

Dr. SPOTTISWOODE CAMERON, in his remarks on the Notification of Phthisis, passed rapidly over the familiar ground of the importance of preventive measures in combating tuberculosis. He thought that the objections that would probably be raised against the notification of phthisis were of three kinds. 1. There was the important one of breach of confidence. The statutory obligation to report certain cases had in regard to such diseases done away with this difficulty; but in regard to phthisis, which was not at it not, ho mission of the patien the notification was valueless. This, In answer to this it was contended: (a) that kno cases enabled the sanitary authority to disinfect at intervals rooms occupied by phthisical patients; (b) it enabled them to suggest in some cases a certain amount of isolation and would indirectly lead to the strengthening of the hands of those who wished to see proper hospital accommodation provided for patients of this class; (c) again, the visit of the sanitary officer would often lead to dealing with such sanitary shortcomings as the overcrowding of dwellings; (d) notification would have the effect of educating the public as to the communicability of the disease and by the distribution of handbills and by friendly explanation do something to overcome the crass ignorance on this subject, especially of the poorer classes; (e) not the least important, perhaps, of the advantages which might be expected from notification would be the greater opportunity it would give the health officer of getting at the causes of the disease. Inquiring back from recent cases he would visit workplaces where the patients had been employed, ascertain perhaps that other sources of infection existed there, and remove conditions favourable to the spread of the disease. 3. The third objection might be that the system was impracticable. The best reply to this was that it was already in action. Dr. Cameron then referred to what has been done in some other large centres, and especially in Manchester. They were fortunate in having amongst them that evening Dr. J. Niven of Manchester who would no doubt explain to them the steps which had been taken in that city in this direction.—In response to the invitation of the Chairman, Dr. NIVEN described how the 500 cases which had been notified from public institutions in Manchester since September last had been dealt with Every one of these cases had been visited by a medical man appointed for that purpose. The patient and his friends were personally instructed how to deal with the sputum to prevent its becoming dry and pulverised. He advised as to the disinfection of the rooms, reported on the source of infection and conditions of overcrowding, and investigated as to the source of the disease. The case then was placed on the list of the lady visitors, of whom the corporation had several. One of these ladies visited the house at intervals and saw that the measures advised were carried out, giving such assistance and advice as might be required. Up to the present the cases reported were chiefly well-marked ones, so that it had not been necessary to make arrangements for an examination of the sputum. This might b required when notification became more general. Ther were many advantages in having begun in Manchester wit the modified notification of institution cases. They ha learnt much and had got their machinery into worki order. In regard to disinfection their most usual plan w to wash the walls down with a weak solution of chloride lime, as recommended by Professor Delépine. They regar the "clean down" as one of the essentials with dirty ho holds. Speaking of the infectivity of phthisis, Dr. N mentioned that an investigation into the causation a large number of fatal cases of phthisis had sh that in half of them there had been opportunities o infection from other cases of the disease.—Mr. H. J. ROPER thought that general practitioners were capable of diagnosing their own cases of phthisis and said that in his experience instructions such as those mentioned by Dr. NIVEN—viz., the using of spittoons containing carbolic acid or some other disinfectant to receive the expectoration, and the avoidance of the use of handkerchiefs, together with free ventilation of the apartments—were usually given by medical men to their phthisical patients in the ordinary routine of practice.—Dr. E. F. TREVELYAN thought that if the sanitary authorities were responsible for the public health it was only reasonable that facilities should be afforded them of satisfactorily coping with the infective diseases, and notification was one such facility. The notification of phthisis would undoubtedly enable them to lessen the mortality from phthisis, which i Leeds itself was over 600 per annum. With this notifica tion the all-important question of educating the patien in regard to the spread of the disease to those abo him became easier Even now every phthisical hospital o patient should receive simple printed instructions to ena him to avoid communicating the disease to others. T notification of phthisis and its diagnosis were closely related subjects. In some early cases it was impossible to make a certain diagnosis from the physical examination even when taken in conjunction with the symptoms; in a proportion of such cases an examination of the sputum would be of assistance. Therefore he was in favour of the sanitary authority making provision for the examination of sputum of suspected cases free of charge, in the same way as was done for diphtheria and some other diseases. Dr. Trevelyan did not think that the notification of phthisis, judiciously carried out, should give rise to any friction between the medical profession and the sanitary authority.—Mr. J. HOLMES cordially agreed with what Dr. Cameron had said. He thought that not only should notification be adopted but that institutions should be provided for the treatment of the phthisical.—Dr. T. JOHNSTONE, medical officer of health of Ilkley, thought that phthisis, like all other infectious and contagious diseases, should be notified.—Dr. SANDERSON LONG and Dr. BRONNER also took part in the discussion and after some remarks from the CHAIRMAN Dr. CAMERON and Dr. NIVEN replied.

Dr. T. CHURTON read notes of cases of Severe Gonorrhœal Arthritis, a few simple, others complicated with rheumatism or with syphilis or both, in which the duration of the disease was apparently very much lessened by the frequent administration of sandal-wood and other oils, salicylates, and mercury.—Mr. T. R. JESSOP, Mr. E. SOLLY, Mr. B. G. A. MOYNIHAN, and Mr. J. W. DRAPER took part in the discussion and Dr. CHURTON replied.

Mr. H. LITTLEWOOD showed. 1. A patient on whom he had performed a month ago Pyloroplasty for Pyloric Stenosis due to Ulcer. The patient was a woman, 36 years of age, who had lost four stones in weight during the last 18 months and had vomited almost daily during that time. She had only vomited once since the operation and is now taking ordinary diet. 2. An Ovarian Cyst with a Twisted Pedicle and a specimen of Osteitis Deformans of the Tibia and Fibula.

The following cases, pathological specimens, &c., were exhibited:—

Mr. PRIDGIN TEALE: Tumour of the Breast.

Dr. E. O. CROFT: (1) The Uterine Appendages removed by Laparotomy, showing Tubo-ovarian Abscess; (2) a Calculus (weight 232 grains) removed from the Female Bladder by Vaginal Cystotomy; (3) a Calculus (weight five grains) passed spontaneously from the Female Bladder.

Dr. T. WARDROP GRIFFITH: (1) Two specimens of Stricture of the Œsophagus; (2) specimens of Rheumatoid Arthritis; (3) Rheumatoid Arthritis in a child following on Measles.

Mr. SECKER WALKER: A Diagrammatic Model of the Eye, designed for the teaching of refraction and accommodation.

Dr. CHURTON: (1) A Child with Anasarca without Albuminuria, but with Excessive Indicanuria; (2) a specimen of Cystin in the Urine.

Mr. MAYO ROBSON: Enlarged Axillary Glands (small round celled sarcoma) of a few months' growth, secondary to a tumour of the breast (primarily an adenoma) of 16 years' duration.

Dr. TREVELYAN: (1) A case of Laryngeal Disease in a Child, probably due to Congenital Syphilis; (2) specimens of the Diphtheria Bacillus from a case of Primary Diphtheritic Stomatitis.

Dr. BRONNER (Bradford): Large Cholesteatoma removed from the Upper Part of the Middle Ear (attic); no subjective symptoms.

Mr. B. G. A. MOYNIHAN: (1) Two cases of Traumatic Birth Palsy; (2) Congenital Deformity of the Hands; (3) a case of Charcot's Disease of both Knee joints.

Dr. J. B. HELLIER: The Uterus from a case of Eclampsia, showing Placental Site.

Mr. E. WARD: An Epithelioma of the Forearm.

Mr. P. J. CAMMIDGE: A Ruptured Liver.

Mr. LAWFORD KNAGGS: (1) Primary Resection of the Bowel for extensive Ulceration and Perforation in a Hernia (specimen and patient). (2) Gangrene of the Bowel and Hernial Sac, Primary Resection.

Mr. A. L. WHITEHEAD: (1) Case of Bilateral Paralysis of the Third Nerve; (2) skiagram of Steel Chipping in the Eyeball.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held at Hanover-square on Jan. 26th, the President, Dr. Ivor Murray (Scarborough), being in the chair.—Dr. Harry Campbell opened a discussion on the Treatment of Diseases of the Nervous System and Nervous Affections by Baths and Climate. He remarked upon the beneficial influence of mere change of air, which he connected with the wandering habits of primitive man. The open-air treatment was, he contended, beneficial in other diseases than phthisis, notably in nervous diseases. He referred to the large part which toxins played in neuropathology and to the potent influence of climate and baths on metabolism, and therefore on the toxicity of the blood. It was often advisable to put nervous patients through a preliminary treatment before sending them away, otherwise they might not benefit by the change. Dr. Campbell held that British health resorts were not so well equipped for the treatment of neurasthenia as some of the continental ones. He referred to the advantage of reducing high arterial tension in some nervous affections, and concluded by inviting discussion regarding the climatic and balneological treatment of sleeplessness, neuralgia, Graves's disease, epilepsy, chronic alcoholism, and morphomania.—Dr. Symes Thompson having testified to the importance of change of environment in functional and organic nervous diseases, Dr. Risien Russell instanced in illustration of the good to be obtained from baths in the treatment of chronic organic affections of the nervous system their ameliorating effect on certain troublesome symptoms in some diseases of the spinal cord. Peripheral neuritis was chosen to exemplify the beneficial effects of this mode of treatment in certain acute affections of the nervous system, but he insisted on *the deleterious consequences to be expected from the* indiscriminate use of baths in many other acute organic diseases. On turning to the consideration of functional affections neurasthenia was selected as an example of an affection the different varieties of which call for very different forms of bath treatment. The neurasthenic subject who required stimulating might derive much good from the cold bath properly given, while another class of neurasthenic patients might be injuriously affected by this measure and might nevertheless obtain benefit from the indifferent bath.—Dr. Bezly Thorne agreed with Dr. Harry Campbell in the opinion that auto-intoxication exercised a dominant influence in the causation of the greater part of nerve diseases. He believed that the influence of climate and of baths in relation to insomnia depended on whether they raised or lowered intra-arterial pressure. He had observed that in certain cases in which baths increased high tension insomnia was aggravated and *vice versâ*.—Dr. Karl Grube of Neuenahr said that he had often been struck by the small attention that had been paid in England to the balneological treatment of nervous diseases. Neither in the handbooks on nervous diseases nor in the books of balneo-therapeutics was sufficient mention made of this valuable form of treatment. This to him seemed all the more remarkable as some forms of nervous disease which were particularly benefited by bath treatment seemed to be very frequent in this country, as, for instance, neuritis. He had always found baths very effective in the treatment of neuritis, especially of those forms of neuritis with a great deal of pain. With regard to the various methods of bath treatment in nervous diseases Dr. Grube had found one rule of the greatest importance, and which might be expressed in the words, "Avoid extreme temperatures." Neither very hot nor cold baths seemed to do much good; on the contrary, they very often did harm by increasing the symptoms by their irritating influence. Indifferent baths—i.e., baths of a temperature of about blood-heat—were most beneficial. The nature of the water used—i.e., its chemical constituents—was only of very secondary influence.—Dr. Fletcher Beach said that in two cases, one of lateral sclerosis and one of tabes, which had been under his care the patients had been much benefited by residence at the seaside. The first patient had considerably improved and the lightning pains of the second patient had much diminished. Open-air treatment was especially desirable for mental as well as for nervous diseases and in all asylums patients were given as much open air as possible. Thus all asylums had large airing courts, and those patients who were fit for it were employed in the garden or on the farm. The nervous system was thereby strengthened and recovery was assisted. In some cases of neurasthenia rest was desirable, and travelling or touring round the world did more harm than good. The effect of altitude on nervous disease varied; some patients improved, while others, especially those in whom sleeplessness was produced, deteriorated and had to live at a lower level. The absence of a complete system of baths attached to hospitals was a defect.—Dr. Fortescue Fox (Strathpeffer Spa) remarked that baths were of advantage, not in advanced disease (sclerosis), but in the early stages of such disease, and in many nervous disorders, especially those manifested by irritability and exhaustion.—Dr. Leon (Sidmouth) said that high altitudes and a dry bracing air had a vaso-constrictor influence, while the opposite applied to a low-lying humid situation, where the arterioles were dilated and the blood-pressure was low. Sleeplessness was common at high altitudes, and in this relation an article recently published showed the valuable effects of vaso-dilator drugs on the sleeplessness and restlessness of old age.

Sheffield Medico Chirurgical Society.—A meeting of this society was held on Jan. 18th, Dr. D. Burgess, the President, being in the chair.—Dr. Arthur Hall introduced a case showing the remains of Vaccination Pustules on the "Chapped Hands" of a girl, aged 15 years, who had not previously been vaccinated, and who about a month previously had nursed a recently vaccinated baby.—Dr. R. W. Gilmour showed a specimen of Adenoma of the Kidney from a patient who had died from apoplexy.—Dr. S. Riseley read the notes of a case of Abscess of the Brain following injury to the eyelid. The patient was a boy, aged one year, who was admitted to the Royal Hospital, Sheffield, on Oct. 20th, 1899, suffering from an abscess in the left upper eyelid; the lid was very prominent, dull-red, and glazed looking, and there was a small wound with sloughy edges and distinct fluctuation. Three weeks previously the child had run a rusty sharp-pointed file-maker's tool into the eyelid for about an inch. The wound did well for a time and then began to swell up. The wound was incised transversely and an excessive amount of pus escaped and on introducing the finger bare bone was felt. The wound was plugged with iodoform gauze. The temperature remained subnormal and the child apparently did well until the second night when meningitis set in; the temperature rose to 100° F., and the child died. Towards the last the eyeball could be seen apparently quite normal. There was escape of cerebral spinal fluid from the wound. The post-mortem examination showed a fracture of the orbital surface of the frontal bone. Lymph covered the brain on the upper and under surfaces, and on the under surface of the frontal lobe there was an abscess of the size of a large walnut, communicating through the fracture with the wound of the eyelid. The abscess cavity contained a little pus and some iodoform crystals and was lined with pyogenic membrane.—Dr. N. D. Bardswell read a report on eight months' trial of the Sanatorium Treatment of Phthisis at the Sheffield Royal Infirmary.[1] Accommodation had been made for 20 patients, but the conditions under which the trial had been made were disadvantageous. In the grounds hammock chairs protected by screens, &c., were provided for the patients, and a revolving shelter had been erected for accommodation in bad weather. Routine treatment had been for the most part modelled on that followed at Nordrach. Apyrexial patients spent the whole day in the grounds; those with pyrexia lay by open windows, the wards being well-aired throughout the night. Three chief meals were given—viz., at 6 A.M., 12.30 P.M., and 7 P.M. Extra butter, milk, and eggs were added to the infirmary "full diet," the diet being modified for individual cases when necessary. Carefully regulated walking exercise was allowed in cases where the temperature was never above 100 2° F. Pulmonary gymnastics were also employed in convalescing cases, systematic massage replacing exercise in bad cases. Practically no medicines were given except bitter tonics, cod-liver oil, and malt. Four-hourly temperatures were taken in the axilla, the pulse and temperature rates were recorded night and morning, the sputum was measured and recorded daily in drachms, and the weight was recorded weekly. In all 30 patients had been treated, 18 of them being still in the infirmary. The cases were unselected. By far the best results had been obtained in patients with a small amount of active disease and good general condition. Out of 17 such cases five had been nearly cured and had returned to suitable work and the rest were very much improved in every respect. Patients with extensive active disease and severe constitutional disturbance and those with phthisis laryngea had done badly, half of them dying and the rest improving in the summer to remain stationary or to relapse in the winter. As far as Sheffield Infirmary was concerned nearly all patients improved considerably under treatment from April to September, but during the winter months all except those with small lesions or those who were well advanced towards convalescence either ceased to improve or became worse.

Newcastle-on-Tyne Clinical Society.—A meeting of this society was held on Jan. 18th, the President, Mr. H. B. Angus, being in the chair.—Dr. W. P. Richardson showed a male child, aged 20 months, with Symmetrical Gangrene of the Feet of one week's duration, the result of Raynaud's Disease.—The President showed a man, aged 44 years, a miner, who was admitted to the Royal Infirmary with a swelling on the right side of the neck of two months' duration.—The members present were mostly of opinion that it was a dermoid cyst and this diagnosis was verified on removal of the tumour on the following day.—The President also showed a man, aged 66 years, with a large, irregular swelling of the neck of four years' duration, which had increased more rapidly during the last two years and was stated to frequently diminish in size towards night. It chiefly involved the right lateral lobe of the thyroid, reaching down to the clavicle and sternum. The diagnosis rested between malignant disease of the thyroid or a simple adenoma. The former was considered the more likely and surgical interference was not thought advisable.—Dr. W. E. Alderson showed a man aged 55 years with Dupuytren's Contraction present in both Hands. His occupation was that of an iron-turner which necessitated incessant pressure on the palms of both hands alike. 12 months ago stiffness unaccompanied by pain appeared in the right hand and the middle finger became gradually flexed. Six months later a similar condition appeared in the left hand, the ring finger being affected. Three months ago the patient sustained a severe lacerated wound of this affected finger which necessitated amputation on account of the tardy nature of the healing process. There was no hereditary influence, and no history of gout or syphilis, but the patient suffered considerably from muscular rheumatism. In the right hand a tense band could be felt running from the centre of the palm to the head of the third metacarpal bone where it crossed the interdigital cleft between the middle and index fingers to reach the outer side of the first phalanx of the former. Another band could be felt passing in the line of the transverse ligament to the index finger and a similar one between the index finger and thumb. The ring finger was affected to a slighter extent. The skin over the bands was adherent and puckered. The first and second phalanges of the affected digits were acutely flexed, whilst the third phalanx was extended. Adams's subcutaneous operation was advised and would be performed soon.—The President showed a man, aged 46 years, who had suffered from Dupuytren's Contraction of both Hands for four years. Both began to be affected about the same time and in each case the condition commenced in the ring finger and then affected the little finger. The man was a labourer and used tools which exerted pressure in the palms of the hands. During the last two years Adams's subcutaneous operation had been performed on three occasions and the hands had been splinted at night. In spite of this the contraction reappeared and last year an open operation was performed on one hand and the dense cicatricial band was dissected out. The result was excellent, although pressure on the scar caused pain. There seemed to be a predisposition to this condition in persons whose tissues were prone to undergo fibroid changes, whether from alcohol, syphilis, rheumatism, or gout.—Dr. A. H. Hobbs showed a curious case of Hysteria. The patient was a well-developed girl, aged 16 years, from whose left breast he had removed three sewing-needles which she had herself inserted. On examination several more were to be felt both subcutaneously and buried deep in the gland. No suppuration or enlargement of the axillary lymphatics had occurred; some pain and tenderness were present. The case was of interest as showing how much pain such patients would voluntarily inflict on themselves.—Mr. J. Clay read a paper on Cæsarean Section, touching chiefly upon the most satisfactory procedures for performing the operation.

---

SOCIETY OF ANÆSTHETISTS.—A meeting of this society was held on Feb. 2nd, the President, Dr. J. F. W. Silk, being in the chair.—A discussion on the After-effects of Ether Inhalation upon the Respiratory System was opened by Mr. Sydney Rumboll (Leeds) who, in 1500 cases of the administration of ether preceded by gas, had only met with one case of bronchitis, one of pneumonia, and four of slight bronchial irritation; but in 60 per cent. of his earlier cases and in 30 per cent. of the last 400 the salivary and bronchial secretions were considerably increased, though quickly relieved after the first or second act of vomiting. These 1500 cases included every variety of surgical operation and were in no way specially selected; some had albumin in the urine, four had small quantities of sugar, and several had cardiac disease. Mr. Rumboll always used his own inhaler which was carefully disinfected before each administration, and in the earlier cases "anæsthetic ether," specific gravity 1017, was employed, but latterly "ether purissimus" of specific gravity 1020. He considered that in every sense the less ether used the better. The operating theatre was always kept at a temperature of 70° F., and every care was taken to prevent undue exposure of the patient. The time of year did not seem to make any appreciable difference to the amount of bronchial irritation; but catarrhal conditions were allowed to subside before any operation was undertaken. Of the six cases quoted Mr. Rumboll believed that the case of bronchitis was due to the cold operating room; the pneumonia was attributed partly to septic infection.—The President thanked Mr. Rumboll for his paper and read a letter from Dr. Macnaughton-Jones in which he stated that in his experience of ether of 30 years he had not noticed a single case of serious respiratory trouble following its use.—Mrs Stanley Boyd read notes of six cases of respiratory trouble which had occurred in her experience during the four years 1895-98. Of these one was a case of lobar pneumonia, one of broncho-pneumonia, and four of more or less severe bronchitis. Five of these cases were abdominal sections.—Dr. Edwin Starling drew attention to the fact that of the cases referred to the majority occurred after abdominal operation, and he related a case of ovariotomy in which a fatal result followed in 36 hours from bronchitis and pulmonary œdema.—Miss Aldrich-Blake stated that at the Royal Free Hospital from 1895 to 1898 1250 ether administrations were recorded, and of these only three developed any serious pulmonary trouble. One of these was a case of operation for injury to the chest wall, which was followed in three days by pneumonia; in another the pre-existing physical signs of phthisis were considerably increased; and in the third, a case of radical cure of hernia, rusty sputum was noticed three days after the administration.—On the motion of Dr Dudley Buxton, seconded by Mr. Noble, the discussion was adjourned, and the President expressed the hope that at the next meeting of the society on March 2nd further facts in elucidation of this very important and interesting subject would be brought forward.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Kent Dispensary on Feb. 2nd, the President, Mr. C. J. Parke, being in the chair. Three new members having been elected the house surgeon of the Miller Hospital (for Mr. Poland) exhibited a case of Tumour of the Scrotum. Dr Septimus Sunderland then read a paper on Some Cases of Pelvic Pain in which the Diagnosis was Difficult. The paper was discussed by the President, Dr. F. S. Toogood, Mr A. E. Joscelyne, Dr. Leonard Williams, Mr. G. C. Williams, Dr. F. J. L. Hart, and Dr. J H. Keay. The meeting then adjourned until March 2nd when there will be a clinical evening.

CHARD WATER-SUPPLY.—At the meeting of the Chard Town Council held on Jan. 30th it was stated that the solicitors of Earl Poulett had reported that Mr Justice Kekewich had granted a period of six months for the council to carry into effect their proposed new scheme of drainage, consequently the threatened proceedings of Earl Poulett against the town council for the alleged pollution of the Chard reservoir by the discharge of sewage would be rescinded.

Reviews and Notices of Books.

Progressive Medicine: A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by HOBART AMORY HARE, M.D., Professor of Therapeutics and Materia Medica to the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital, &c. Vol. I., pp. 490, Vol. II., pp. 468. Vol. III., pp. 440. 1899. London: Henry Kimpton. Price 12*s.* 6*d.* each volume.

UNDER the somewhat cryptic title of "Progressive Medicine" appears a new periodical publication the intention of which is to provide medical men with the latest information as to the progress which is being made in the various departments of medicine and surgery. Many attempts have been made from time to time to record in a comparatively small space all new facts that have been published during the year, but in most cases the result is likely to be almost useless, as the valuable observations and records of the year have not been separated from those which are unworthy of being permanently recorded. This work is a quarterly publication which contains articles on all the branches of medical science, each one written by a recognised authority on that particular subject; in each article the additions to our knowledge, which are of value from their own intrinsic merit, are arranged in a readable and well-digested form. The whole of medicine and surgery are divided up among the four volumes which appear in one year, and that there may be a real uniformity in the work the general editor, Dr. H A. Hare, has exercised a careful supervision over the individual articles. The first article of the first volume deals with the surgery of the head, neck, and chest, and is written by Dr. J. C. Da Costa. It commences with an account of the modern surgical treatment of exophthalmic goitre; the operative procedures which are most strongly recommended are described and discussed and then the author sums up our present knowledge in a few sentences. Not every subject is dealt with, only those being noticed in which some valuable addition to our knowledge has recently been made. For example, we may refer to an article of this same section in which Dr. Da Costa describes the treatment of wounds of the lung; here we find an interesting account of wounds of the lungs by bullets and we are told that Dr. Senn in the late Spanish-American war found that many patients who had been shot through the lung with a Mauser bullet recovered under the treatment of rendering the surface aseptic and sealing the wound hermetically. Few cases of hæmothorax require operation, but the author gives a brief account of a case under his own care in which severe secondary hæmorrhage from a wounded lung occurred into the pleural cavity; the chest wall was laid open and more than a gallon of blood was removed. The bleeding lung was surrounded by packing which arrested the hæmorrhage and the man ultimately recovered. During the operation two quarts of saline fluid were introduced into the median basilic vein.

It is obviously impossible to describe fully the contents of these very interesting volumes but we will mention the names of the writers who have contributed the several articles.

Dr. Alexander D. Blackader of the McGill University, Montreal, is responsible for the article on the Diseases of Children. Dr. Ludvig Hekboen, Professor of Pathology in the Rush Medical College, Chicago, has written on Pathology. Dr. W. S. Thayer has contributed the article on the Infectious Diseases, including Croupous Pneumonia. This contains a long and valuable account of the present state of our knowledge of malaria and the malarial parasite. In the section on Typhoid Fever the author gives a summary of

Bushnyco's method of treating the disease by a liberal diet, consisting of bread, boiled meat, a cutlet, soup, milk, and an egg. So far as can be judged from statistics founded on 154 cases, in 80 of which the diet was adopted while the remaining 74 were fed on milk only, the cases treated by the fuller diet have a slightly higher percentage of recoveries and a shorter stay in hospital. Dr. Thayer in commenting on this diet asks, "Is it not more than likely that many cases of typhoid fever suffer from too restricted a diet?"

Dr. A. Logan Turner of Edinburgh has written the article on Laryngology and Rhinology, and Dr. Robert L. Randolph of the Johns Hopkins University, Baltimore, has supplied the section on Otology.

The second volume commences with an account of the Surgery of the Abdomen, by Dr. William B. Coley, who occupies 140 pages with an excellent *résumé* of all that is new in this department of surgery. Perhaps the most interesting, and certainly the fullest, description is given of the operative treatment of hernia and many useful illustrations accompany it. Dr. W. S. Halstead is quoted as saying that "the licence to practise general surgery should be withheld from those who have not practised on animals the operation for circular suture of the intestine and intestinal anastomosis." There is a great fallacy in this recommendation, for the intestinal wall in dogs is decidedly thicker and therefore more easily sewn than is the wall of the human bowel.

Dr. J. G. Clark of the Johns Hopkins University, Baltimore, deals with the subject of Gynæcology, and amongst other things he discusses fully a valuable paper by Abel on the methods of abdominal suture and their relationship to the production of post-operative hernia, with very careful statistics which show clearly that this form of hernia is least common when the fascial layers have been carefully brought together.[1]

Dr. Alfred Stengel of the University of Pennsylvania writes on the Diseases of the Blood, Diathetic and Metabolic Diseases, and Diseases of the Spleen, Thyroid Gland, and the Lymphatic System, giving an especially interesting account of diabetes mellitus. The concluding article in the second volume, on Ophthalmology, is from the pen of Dr. Edward Jackson of Philadelphia and occupies 90 pages; it is carefully and concisely written.

The third volume commences with an account of the Diseases of the Heart and Lungs by Dr. William Ewart of St. George's Hospital. It ranges over an extensive area and is judiciously moderate in its estimation of the value of the many recently advocated therapeutic measures for the treatment of diseases of these organs. Dr. Stelwagon of Philadelphia writes on the Diseases of the Skin. The case of chromidrosis which is described was in all probability due to malingering, although it is stated that it was found that the manifestation was not artificial. The article represents very adequately all that has recently been done in this department.

Dr. W. G. Spiller of Philadelphia has contributed the account of the Diseases of the Nervous System and Dr. R. C. Norris that of Obstetrics. They are both very satisfactory and we may especially mention in Dr. Norris's article the section on the Surgery of Obstetrics.

These volumes are well printed on good paper in clear type; they should prove of value to every medical man.

The Races of Man: an Outline of Anthropology and Ethnography. By J. DENIKER, Sc.D. Paris, Chief Librarian of the Museum of Natural History, Paris. The Contemporary Science Series. London: Walter Scott, Limited.

THIS handy volume is designed for the use of those who wish to obtain rapidly, from a trustworthy source, some general notion of the ethnographic and anthropological sciences, and to understand the foundations on which they are based. Some knowledge of these subjects of scientific inquiry is desirable as prefatory to, and concomitant with, the study of men and diseases among the many nationalities of the British Empire which includes races so essentially different as negroes, Arabs, Bushmen, and many cultivated Eastern races. The medical officer who is called upon to introduce hygienic measures for the removal and prevention of disease will find it important to acquire some knowledge of the people with whom he has to deal; the means to be employed for eradicating ophthalmia or malarial fever should be based upon some knowledge of the physical characters of the people to be dealt with as well as of the nature of disease; while an appreciation of their laws, habits, and customs may have a distinct bearing on a decision as to the wisest methods of carrying into practice the necessary sanitary arrangements.

Local customs as well as endemic diseases are well worthy of study; it may be found that particular ethnical groups in a locality show recognisable forms of proneness to, or exemption from, special diseases. Every country has its own varieties of physical type, language, manners, and customs—matters of as much importance to the physician as their psychical peculiarities and religion are to the governor and the teacher. The simplest and best established methods of anthropological observation may be usefully adapted to clinical study as indicating noteworthy points and showing what to look at, and what to look for, in the individual case.

The volume before us fully maintains the reputation of the Contemporary Scientific Series. The author speaks with a full knowledge of his subject and experience gained as librarian of the Museum of Natural History, Paris. He writes with the intention of imparting to the reader as much well-arranged information as is possible within the compass of his book as a stimulus to the student rather than as a complete account of anthropology as a science. The book is the more readable as Dr. Deniker, while enthusiastic in his work, does not attempt to impress any predominant theory of his own. The purpose of the author is to place before the reader in simple form the essential facts of the twin sciences of anthropology and ethnology, and while at times expressing his personal opinions on many questions of anthropology in general, such as "the classification of states of civilisation," he refrains from reiterating any predominant views of importance to the special student of anthropology only, or otherwise diverting attention from the main object of interesting and informing the reader upon the subjects dealt with.

Looking at the races of man the definite facts before us are the groups of mankind presented as Arabs, Swiss, Australians, Bushmen, Siouan Indians, &c. These do not represent unions of individuals which, in spite of some slight dissimilarities, are capable of forming what zoologists call "species" or "varieties" in the case of wild animals, or "races" in the case of domestic animals. They are *ethnic groups* formed by virtue of community of language, religion, social institutions, &c., which have the power of uniting human beings of one or several species, races, and varieties. The social groups are formed by the union of individuals belonging usually to two, three, or a greater number of "somatological units" known by aggregations of physical characteristics such as physiognomy, stature, or anthropometrical and physiological peculiarities combined in a certain way. A distinction is then to be drawn clearly between the ethnical and somatic groups; in other words these two important modes of classification must be clearly understood and distinguished.

There are certain somatic characters distinctive of man and apes; the erect attitude, curvature of the spine, the size and structure of the brain, and the morphology of the skull and the teeth; these differences being less accentuated in the fœtus and in the young than at the stage of adult development. Distinctive characters of man are found in (1) morphological development as studied anatomically, and (2) in physiological and psychological peculiarities; these differ much in their variations according to sex, age, and race. It is interesting and instructive to note the points which scientific research has shown as the most distinctive somatic characters of the human races, for these are also worthy of record in the description of individuals in clinical study, especially when recording the personal equation of the individual or the signs of degeneration, whether a reversion in type or an example of decadence following inheritance of an adverse environment. Among morphological characters cranial measurements stand first, but the author acknowledges that "peoples or ethnic groups being formed of various elements, it is in most cases impossible to determine, after the examination of an isolated skull, to which population it belongs; all that can be said is that the skull is brachy- or dolicho-cephalic, orthognathous or prognathous, &c." Stature varies in each race with sex, age, and external agencies, but at the same time it is true that these variations are also produced in a similar way in all races and cannot exceed certain limits imposed by race.

This interesting work is mainly descriptive of the ethnical characters of the human races, including their linguistic and sociological characters as well as an account of the European, Asiatic, African, Oceanic, and American peoples. The illustrations, to the number of 175, are well executed, mostly from original photographs, and indices of bibliography and of the subjects treated add value to the volume.

Experiments on Animals. By STEPHEN PAGET, F.R.C.S. Eng. With an introduction by Lord LISTER. London: Baillière, Tindall, and Cox. 1900. Pp. 274. Price 6*s.*

IN this work Mr. Stephen Paget has placed before those of the public who care to read it the evidence that has led the vast majority of the profession to approve of vivisection when performed, not carelessly or thoughtlessly as boys harry a toad or hunt a cat, but with some distinct object in view, or for the resolution of some problem which cannot otherwise be settled, or for the direct advantage of man or animal. Commencing with Galen, who showed that the brain was hot and not cold as was then generally believed and that the arteries contained blood, he passes in review the experiments of Realdus Columbus and the far more important ones of Hales and Harvey, and shows how important a bearing they had on the advance of physiological knowledge, and especially on the physiology of the circulation, and how this again assisted the progress of surgery. The knowledge of the certainty and constancy of the establishment of the collateral circulation after the ligature of an artery, which could only be learnt by experiment on the living animal, enabled Hunter to anticipate recovery after ligature of a large artery in cases of aneurysm and to replace by that operation the far more fatal one of amputation which was then generally adopted. In the next chapter the value of the experimental method is insisted on in regard to digestion by comparing the knowledge of that process possessed by the ancients with that which followed the experiments on the living animal performed by Réaumur, Spallanzani, Dr. Beaumont, and Claude Bernard. The discoveries made by the last-named experimenter on the glycogenic function of the liver are shown by Mr. Paget to have had great influence on our theory and treatment of diabetes. He then points out the value of experiments performed by Du Hamel, Bichat, Stanley, and others on living bone in demonstrating the function of the periosteum and in promoting the surgery of the osseous system. Still more important has been the practice of vivisection in determining the function of the nervous system and consequently the proper practice of medicine; and Mr. Paget rightly observes, "If a better understanding of the nervous system could have been got without experiments on animals why had men to wait so long for it? The Italian anatomists had long ago given them all the anatomy that could help them. The hospitals and practice had given them clinical facts for many hundred years; nervous diseases and head injuries were common enough in the middle ages, and by the time of Ambroise Paré, if not before, post mortem examinations were allowed. The one thing wanted was the experimental method and for want of it the physiology of the nervous system stood still." That method was adopted with the best results by Bell, Magendie, Marshall Hall, Flourens, Bernard, and the numerous experimenters of the present day. We have not space to comment on the chapters which Mr. Paget devotes to inflammation, suppuration and blood-poisoning, anthrax, tubercle, diphtheria, rabies, cholera, plague, malaria, and poisoning by snake venom, but in each and all of these conditions he dwells on the immense value of the researches that have been undertaken upon living animals in following out the nature and course of disease and the benefits that have been derived from this mode of investigation. The only omission which we have noticed is that of skin grafting. The questions discussed by Mr. Paget have been carefully considered by him in his capacity of secretary to the Association for the Advancement of Medicine by Research and the perusal of his work will satisfy all but fanatics that experiments on living animals when undertaken with a due regard to the objects in view have proved of the greatest importance in the progress of medicine; and it may be added that in a large number of instances the risks and dangers which such operations involve would be cheerfully undergone by the operators themselves.

A Manual of Surgery for Students and Practitioners. By WILLIAM ROSE, M.B., B.S. Lond., F.R.C.S. Eng., Professor of Clinical Surgery in King's College, London, and Senior Surgeon to King's College Hospital; and ALBERT CARLESS, M.S. Lond., F.R.C.S. Eng., Surgeon to King's College Hospital and Teacher of Operative Surgery in King's College, London. Second edition. London: Baillière, Tindall, and Cox. 1899. 8vo, pp. 1190. 400 Illustrations. Price 21*s.* net.

WE were able to speak with much approval of this work when it first appeared and we are glad to see that it has been so much appreciated by the professional public that already a second edition has been called for. The whole of the text has been revised and parts have been rewritten; some illustrations have been omitted and others added; much new material has also been added, but there has been an increase of only about 30 pages in the size of the book. It may certainly be looked upon as fully up-to-date and there is little with which we cannot agree, but we may mention that the rhinoplastic flap figured on p. 706 is not of a shape best calculated to form a presentable nose; a better shape is that given in THE LANCET of Feb. 21st, 1891, in a paper by Brigade Surgeon-Lieutenant-Colonel Keegan. We would urge the authors not to allow the book to grow any larger, a morbid tendency frequently displayed by otherwise healthy works. At its present size it still forms, as we mentioned in our review of the first volume, the most suitable book for all except the higher examinations in surgery.

The Use of Lead Compounds in Pottery from the Potter's Point of View. By WILLIAM BURTON, F.C.S. London: Simpkin, Marshall, Limited. 1899. Price 1*s.*

THE views of the potter in regard to innocuous glazes must be listened to with respect. Theory may indicate what might be done but practice only can be decisive. Mr. Burton is a director of a large firm of pottery manufacturers and is perfectly prepared to adopt methods which are calculated to alleviate the suffering arising from the use of lead compounds in pottery manufacture. He is not opposed to reform on this head so long as it does not threaten the vital interests of the industry. The little work before us is devoted mainly to a criticism of the report issued by Professor Thorpe and Professor Oliver on the Use of Lead Compounds in Pottery on behalf of the Home Office. He differs from these authorities in regard to the means which they suggest for minimising the evil effects of lead compounds, and gives his reasons why their conclusions can only be very partially adopted in the English pottery trade. His statements are very temperate, in good taste, and reasonable, and regarding the old adage, *audi alteram partem*, must be seriously considered. Mr. Burton holds that much good would be done if the work-people could be prevailed upon to adopt ordinary reasonable care and common sense in obeying the special rules of the Home Office and in using the appliances. It is satisfactory to note that Mr. Burton believes that the time has come when the use of raw lead in glazes may be prohibited and he only asks that sufficient time should be given to those manufacturers who have had no experience in the use of fritted lead compounds to carry out experiments for their adoption. That is a reasonable enough request which the Home Office, as we recently announced, is inclined to grant.

LIBRARY TABLE.

Our Secret Friends and Foes. By PERCY FARADAY FRANKLAND, Ph.D., B Sc., F.R S. Fourth edition, revised and enlarged. London: The Society for Promoting Christian Knowledge. 1899. Pp. 268. Price 3*s*.—Bacteriology is a subject which is not easy to present in popular terms, but Professor Frankland has succeeded well in this little work, for it is written in a very interesting and intelligible way, such as makes it well adapted for the class of readers—the uninitiated—for whom it is intended. The book belongs to the "Romance of Science Series" and is published under the ægis of the General Literature Committee of the Society for Promoting Christian Knowledge. The chapters are based on a series of lectures delivered before popular audiences. The subject matter is, however, expanded by the opportunity which publication affords. The rôle of organisms in disease and in great natural processes is eloquently described. It would be well for the public to read this excellent little story of the ways of bacteria in order that false and dangerous conceptions which are very generally current may be removed. The average man in the street has a curious idea of the microbe in regard to its nature and size and invariably he thinks it a deadly thing which should at all costs be destroyed. An intelligent perusal of Professor Percy Frankland's book will teach him, however, that amongst the myriads of bacteria around us we may count more friends than foes. We are yet merely on the fringe of the subject with regard to those functions possessed by many bacteria which are of importance to the well-being of the human race.

An Introduction to Analytical Chemistry. By D. G. HENDERSON, D Sc., M A., F.I C., and M. A. PARKER, B.Sc. London: Blackie and Son. 1899. Pp. 224 Price 5*s*.—The plan of this book is progressive, the student being introduced first to exercises on characteristic reactions of the metallic salts and the acids and bases before he proceeds to the analytical classification of the metals. Then follows a section on acidimetry and alkalimetry and afterwards an analytical classification of inorganic acid radicles. Having mastered this important part of the subject the student may proceed to the general scheme for the analysis of inorganic substances. The authors have included a useful section on the analysis of alloys. Finally, the grouping of the organic acids connected with a scheme of detection is given, while the characteristics of organic bodies, such as aniline, urea, and follow as being outside any scheme of grouping. We have carefully examined the directions given and we know from practical experience that they are reliable. The application of the spectroscope to analysis might with advantage have been amplified. The book is an excellent laboratory companion for those entering upon a course of elementary analysis.

The Year-book of Pharmacy, 1899. London: J. & A. Churchill.—The thirty-sixth annual meeting of the British Pharmaceutical Conference was held last year at Plymouth, and the transactions of this conference are reported in this volume. This fact, however, by no means forms the most valuable feature of the Year-book. The committee of publication take some considerable trouble to publish concurrently with the transactions abstracts of papers relating to pharmacy, materia medica, and chemistry which have been published in British and foreign journals for the preceding year. In this way the advances that have been made may be seen at a glance. The introductory chapter is an admirable summary of these advances and is a valuable source of reference, as it affords also very instructive reading to the progressive pharmacist. The papers read this year at Plymouth were of unusual interest and not disappointing in number. The conference will meet this year in London. The Year-book is quite up to its usual standard and is full of matters of importance to the pharmaceutical profession.

Practical Hints on the Analysis of Water and Sewage. By SIDNEY BARWISE, M.D. Lond., D P.H. Cantab. London: Rebman, Limited. 1899. Price 2*s*. 6*d*.—This little book is especially written for the use of medical officers of health who, while desiring to make as complete an analysis of water or sewage effluent as is essential yet possess little time for making an elaborate experimental inquiry. The subject could hardly be put in simpler terms both in regard to details of processes and to the construction which may be put upon the results. In this way the book should be of distinct assistance to those requiring a knowledge of the analysis of water and sewage sufficient to enable them to give a definite judgment one way or the other. Apparatus suitable for the special work is described and illustrated. The chapter on bacterioscopic examination of drinking waters is desirably brief and to the point. Dr. Barwise writes with authority on the subject and as the book is the result of his experience of analytical processes and of the interpretation to be placed thereupon it will be consulted with assurance. Further his style of writing and his descriptions are clear so that the essentials of this department of sanitary work will be readily understood by the student and the medical officer.

Examination of Water for Sanitary and Technic Purposes. By HENRY LEFFMANN, A.M., M.D., Ph.D. Philadelphia: P. Blakiston's Son and Co. 1899. Price $1·25c.—Our estimate of this little volume in the review of the original edition was correct, of which the fact that the book has since undergone revision and enlargement for the third time is confirmatory, the present issue being the fourth edition. We cannot note many important changes, and indeed the author admits as much for "no great advance in analytic methods in this field has taken place since the publication of the third edition." The methods prescribed are in very general use, having been stamped by experience as correct, expeditious, and most convenient. The author, however, notes that some change of opinion as to the value of bacteriological examinations has taken place. While bacteriologists at one time were tempted to discredit the value of chemical analysis they were now disposed to admit that up to the present time the detection of pathogenic bacteria in water is so difficult a task as to be rarely accomplished. In the addendum the filtering apparatus devised by Dibdin is described. The name Dibdin is spelt incorrectly Dibden. The utility of this little work is clearly recognised.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 10, 1900.

As medical journalists we have nothing whatever to do with such political questions as do not happen to affect the interests of the medical profession or the health and well-being of the community at large; but we occupy, perhaps on that very account, a position of advantage in that we can regard questions of national interest and public importance from a perfectly independent and impartial standpoint. We can note the trend of public opinion and listen to the reflections and observations of the more thoughtful people among us with a mind unbiased except where we are participating in patriotic feelings which we share in common with most citizens of the British empire. We are sure that our readers hold with us the belief that it would have been well if much of what has been said and published regarding the conduct of the South African war had never seen the light. Apart from the consideration that a good deal of what has appeared on one day, having no foundation in fact, has disappeared on the morrow, the undignified tone of exaggeration and sensationalism adopted by a certain class of journals has been a frequent cause of additional anxiety and pain to those who have relatives or friends at the war, as well as the origin of much needless misapprehension on the part of the public. These things concern the medical profession deeply, for the health of those whose feelings are thus wrung is our particular care. Critics seem to forget when speaking of the war that it is so easy and at the same time so futile to be wise after the event; every speculator would have made his fortune had he known and realised before investing his money all the facts and their relative proportion and importance to one another beforehand. The political situation in South Africa was altogether exceptional and unprecedented and the actors, especially the military commanders, had to accept the position just as it stood under unfavourable conditions. They have not done so badly as the British public has been led to believe. More than that it is not within our province to say.

Members of the medical profession have used their opportunities for estimating the feeling of the army in South Africa, and the intercourse between the sick and wounded and their medical advisers is close. All the misgivings and adverse criticisms which find expression here have had little or no place among those who are fighting our battles in the field. The troops in South Africa seem to be in excellent health and fettle, and confident of success and of the ultimate result of the war. The dominant feeling among the wounded who have arrived in England is to get well enough to return to duty. Could such be the case if they felt that they were serving under incompetent or bungling commanders? There is no such feeling prevalent among those who surely ought to know best. Officers and soldiers have alike recognised that the preparations and arrangements for the campaign have been on a large and liberal scale; they speak in grateful terms of the medical service; and regard the reverses under which our arms still abide as in the main attributable to the adverse conditions under which the war was undertaken—and under which it has had to be carried on up to the present time. It was our pleasure last week to refer to the way in which the officers and men of the Royal Army Medical Corps are bearing themselves as one of the bright spots of the present war; and it is only proper and fitting, at a time when the nation is moved by a widespread and genuine feeling of patriotic enthusiasm, and when so much is being done for the aid and comfort of our soldiers and their families, *that the requirements of the Royal Army Medical Corps in this respect should not be lost sight of. We are very glad, therefore, to announce that the establishment of a Fund for the benefit of that corps has been taken up in earnest. We have already announced the formation of this Fund, and in another column will be found an account of a meeting held in furtherance of this end on Monday last at Sir* DYCE DUCKWORTH'S *residence in Grafton-street.*

It will give the greatest pleasure to the medical profession to help their colleagues of the Royal Army Medical Corps—and the call is, we are glad to say, being handsomely responded to by the heads of the profession—but we think that what is also wanted is a widespread expression of appreciation, sympathy, and good will on the part of the lay public. The work of the Royal Army Medical Corps has been splendidly done on behalf of the wounded sons of the public and deserves to be widely recognised by all. We trust therefore that our readers will bring to the notice of their friends and patients the institution of this Fund. If they do this they can secure for it at once the large patronage that under the circumstances it certainly merits. As far as the amount of the subscriptions go we think that Surgeon-General MUIR'S suggestion, which follows, is sound. The donations should be small, so as to bring the list within the reach of all who are desirous of joining in it—say, half a crown for members of the medical profession throughout the United Kingdom and more or less than that sum for those outside the profession. The labours of the men who have had the proud privilege of caring for the sick and wounded on the battle-fields and in the war hospitals of South Africa, where timely succour has been so sorely needed, have stood out prominently during the present campaign, and we are sure that the Fund in their behalf only needs to be brought to the attention of the public to secure immediate support. We shall be glad to receive and acknowledge subscriptions, which may also be sent to the Treasurer of the Fund, Mrs. CHARTERIS SYMONDS, at 58, Portland-place, W. Contributions in kind should be directed to Miss MAXWELL-MÜLLER, R.R.C., at 100, Victoria-street, S.W.

THE excellent address of Dr. J. F. GOODHART delivered recently before the Reading Pathological Society and published in our columns[1] raised many interesting points worthy of the consideration of our readers. It is not our intention to review that address here, but rather to dwell upon one or two of its lessons. Dr. GOODHART was dealing primarily with the question of "acidity," of uric acid acidity, and with the stereotyped set of ideas which have gathered about this ailment, almost as defined and unvarying as the crystals of uric acid itself. But the main moral of his address was that each individual case is a separate study to be judged independently by the medical practitioner. "I want you all to go back upon your own experience, to put away all that you have read and seen through other people's spectacles, and to observe again afresh and then to answer the question, 'Is it so?'" There is great need for such teaching nowadays, when every symptom has its special medicine and when our consulting rooms have become the receptacle of remedies the very name of which is not to be found in the latest books of materia medica. The medical man must guard against the risk of becoming a slave to any set of ideas, even to his own. The most open-minded practitioner is apt to close up his experience too soon and too confidently, and to overlook aspects and causes and complications of disease which a little more time and insight would disclose to him and the revelation of which would add tenfold to the interest and value of his work. Much more is this true of the practitioner who cannot be called open-minded—he who has a ready label for every case and a routine medicine for its treatment.

---

[1] THE LANCET, Jan. 6th, p. 1.

Dr. GOODHART indicated a source of information not always sufficiently drawn upon by the medical practitioner—the patient. We all know that he who is his own lawyer has a fool for his client. Medical men are not always good therapeutists in their own cases. Much more obvious is it that the judgment of laymen as to their medical care cannot generally be of much value. Medical practitioners, even those whose work lies among the intellectual and influential classes, must often be struck with the obtuseness of clever people in regard to the nature and processes of disease. Geniuses, even, such patients may be, but they cannot understand the simplest medical procedures, either when set in motion for themselves or for the members of their family, and are often more difficult to guide than a plain unsophisticated working man. But there is a way in which every intelligent practitioner finds assistance from the views and experience of his patients. There is often in patients a quick and keen sense of the suitability of medicines or of diet prescribed, and he little knows his profession who does not heed such impressions and take them into his consideration. Dr. GOODHART says of the phenomena of uric acid excess that they form a problem in *animal* chemistry. We might almost say that they form a problem in *personal* chemistry, for the production of excessive uric acid in any given case depends on different factors from those which produce it in another case. One man will suffer from one wine and another from another; a third man will have a severe attack who takes no wine at all, or beer, though it by no means follows that his attacks have no relation to wine or beer drunk by his forefathers. The children's teeth may be set on edge by sour grapes which they have not eaten. A fourth man may owe his attack to overwork and a fifth to cold. In all these things the experience and narrative of a patient will guide the medical man. But we should scarcely go so far as Dr. GOODHART when he says that a man must decide for himself whether he requires a stimulant, or when he seems to leave the selection of that stimulant and its dosage very much to the patient himself. We should have to extend the same principle to women. Surely all physicians, and not only gynæcologists, would say that the feeling of "requiring a stimulant" in women was a dangerous guide for the exhibition of stimulant apart from medical advice.

Dr. GOODHART lamented that men nowadays drink whisky whereas in his early days they drank beer. He says, with no exaggeration we fear, that quite young men often confess to three or four glasses of whisky a day—"a poisonous drink to them, without the least idea of the harm that is accruing to them." It is obvious that such practices are well-nigh suicidal and that men who indulge in them, if they are to be saved from the results of their weakness, must be advised without reference to their own sensations. Dr. GOODHART thinks that medical men are largely responsible for the degree in which whisky is used to the exclusion of honest wines and beer. He says, "We tell everybody to drink whisky." It is serious that so good and so genial a judge of his fellows as Dr. GOODHART should lay at the door of the medical profession this great responsibility, but we believe that his words convey in a general sense the truth. Medical men are too ready to take the patient's tastes and sensations into consideration when they should assume the entire responsibility of advice, while in the matter of the patient's symptoms they may be too ready to think that the sufferer can tell them nothing which they do not know. The subject of diet—and especially of drink—is the last subject on which patients should be allowed to guide the treatment of their cases. The immediate effects of the favourite ingesta are comfortable; the ill-effects are remote and ulterior and cannot be foreseen by the patient. There are certainly times when the patient may be taken into consultation with advantage, but he must not be allowed to dictate either the occasions or the doses of his stimulant, or disaster may follow.

◆

A CASE which may be somewhat trivial in itself, but which is of curious historic interest to the modern representatives of the barber-surgeons, was lately decided in the Court of Appeal. The appellant was a hairdresser who exercised his worldly labour upon the Lord's Day at Wolverhampton and was fined by the stipendiary magistrate to the amount of half a crown and costs. The statute under which the conviction was made provides that no tradesman, artificer, workman or labourer, or other person whatsoever shall do or exercise any worldly labour, business, or work upon the Lord's Day, or any part thereof, works of necessity and charity only excepted. It was not argued that the work was either one of necessity or of charity, but counsel contended that the Act did not apply to barbers and hairdressers because they were not *ejusdem generis* tradesmen, artificers, workmen, or labourers. It was well known, he said, that at the date at which the Act was passed the profession or business of a barber was of more importance than it is at the present time, and that it was formerly associated with that of surgery. Had the legislature desired to forbid this business on Sunday it would have expressly mentioned barbery amongst the occupations which were prohibited. In the reign of HENRY IV. barbers were incorporated in a craft, and surgeons were enjoined for their protection against blood-letting and the craft of barbery. On behalf of the respondent it was contended that the appellant came within the terms of the Act because he earned his living by the work of his hands, but in contradiction to this the appellant's counsel quoted the speech of the cobbler in JULIUS CÆSAR in which he said, "All that I live by is with my awl, I meddle not in tradesmen's matters." In giving judgment Mr. Justice CHANNELL said that they had not to consider whether the appellant was a tradesman within the meaning of the Act. This was rendered unnecessary by the way in which the summons was framed. The court, however, would not base their judgment on that single point because should they do so it might be assumed that the appellant's business came within some of the remaining words of the Act. The Act related to certain specified persons; the words "or other person whatsoever" were to be read *ejusdem generis* with the preceding words. The word "tradesman" was intended to mean a person who carried on the business of buying and selling, an artificer meant someone who had made something; the words "workman or labourer" would not apply to the appellant. The contention of the counsel for the appellant that a barber's was a well-known business and of more importance formerly than at the present time was an additional argument to show that a barber was not one of the persons to whom the Act was intended to apply. Mr. Justice BUCKNILL concurred.

We do not wish to question a decision which will in future prevent the prosecution of hair-dressers in some places for what their fellows might do with impunity in other districts. It is, however, interesting to recall the fact that THOMAS ARUNDEL (FITZALAN), Archbishop of Canterbury in the reign of HENRY V., enjoined that the barbers of London should close their shops on Sundays. On July 24th, 1413, the Primate of All England addressed certain letters to the Lord Mayor and aldermen of the city of London. After telling them that he knew that they sought for the things which were above and that they would on that account readily incline to carry out things which tended to the observance of the Divine law, he intimated that when he was lately presiding at the Provincial Council in London with the Suffragan Bishops and the clergy of the province of Canterbury it was made known to them with universal reprobation that the barbers of the city of London (being without zeal for the law of GOD and not perceiving how that the Lord had blessed the seventh day and made it holy and commanded that it should be observed by no abusive pursuit or servile occupations but rather by a disuse thereof) in their blindness kept their houses and shops patent and open on the seventh day, the Lord's Day namely; and that they followed their craft on the same just as busily as on any other day in the week customary for such work. With the assent of the Suffragans and clergy the Archbishop determined that there must be made a solemn prohibition of the practice, and in future barbers were to be enjoined not to keep their houses open or to follow their craft on the Lord's Day on pain of the greater excommunication. The Archbishop proceeded to say that as the malice of men had increased, a thing to be deplored, temporal punishment was held more in dread than clerical and that which touched the body or purse more than that which killed the soul; he therefore heartily entreated them for the love of GOD and of His law and, moreover, he required and exhorted them, that they should take counsel on the matter and ordain a competent penalty in money to be levied for the chamber of the City or such other purpose as they should think fit upon the barbers who transgressed in future, conceiving that in this way those who did not fear the anger of GOD would be restrained by a scourge inflicted upon their purse.

It should be added that the ordinances formulated by the barbers themselves in the middle ages forbade in the strictest possible terms the shaving of customers on Sundays, while records of the punishment of transgressors in this respect show that the prohibition was continually being enforced, and this during the reigns of the immediate predecessors of King CHARLES II. It cannot therefore be suggested that barbers were intentionally excluded from the provisions of the Lord's Day Observance Act on account of any unwillingness to impose a novel restriction upon them. Nor apparently can they have been exempted on account of any importance of their calling derived from its former connexion with surgery. In support of this alleged connexion the privilege to let blood was referred to. Unfortunately for this argument, the Act of HENRY VIII. which united barbers and surgeons in one company expressly forbade, in London at all events, that barbers should let blood or do any act of surgery except draw teeth, while at the same time, in compensation, surgeons were precluded from shaving their customers. If this was the law in London in the days of HENRY VIII. we doubt whether even in country districts blood-letting was performed as a rule by barbers in the days of CHARLES II.; at any rate we question whether their functions gave them any kind of status akin to that of surgeons, but we have not found any records bearing directly on this point. It seems to us that, however commendable the decision of the Divisional Court may be on account of its ingenuity or its expediency, and however interesting it may be to recall the once intimate relations between barbery and surgery, the present freedom of the barber to break the fourth commandment can hardly be regarded as the revival of an ancient liberty accorded to science by our forefathers.

Annotations.

"Ne quid nimis."

GARBAGE-MONGERS.

AN unusually hideous instance of the crime of garbage-mongering was brought to light at Marlborough-street Police court on Jan 31st and the offender, a man named Stoppani, received a salutary sentence of three months' imprisonment with hard labour. About two tons of stuff in various stages of putrefaction were seized on his premises which were apparently destined to be sold to keepers of cheap restaurants, a detail which brought from the magistrate a reminiscence of how a cosmopolitan waiter had once told him that in no place in Europe was such cheap living to be obtained as in the neighbourhood of Leicester-square. The two tons chiefly consisted of "blown" tins of preserved food of various kinds, many of which had been pricked and re soldered after the escape of the accumulated gases, but three hundredweight of bacon in an advanced state of putrefaction showed that this enterprising merchant did not confine himself to tinned provisions It was further proved that he had bought for a sovereign from a wholesale firm a quantity of tinned goods which, if sound, would have been worth about £30, but which had been "thrown away to be removed for the purpose of being converted into manure," and were invoiced to the buyer by the seller as defective and not fit for human food. With regard to this we are aware of no process by which tins of preserved asparagus, milk, or sardines, can profitably be converted into any form of agricultural fertiliser, and we must point out that neither the selling of such goods with notice of their condition to the purchaser nor the throwing of them away to be removed by the dust collector protects the poorer sections of the public against the future retailing of them as articles of diet. The wholesale firm seems to have safeguarded their position by informing the miscreant buying the garbage from them that what they were selling was unfit for human consumption, of which he must have been fully aware. They do not seem to have troubled themselves to wonder for what other purpose such filth could possibly be thought worth buying at the price given; but even if as an alternative the stuff had been left where it was it would have been a temptation to many persons who might have been in a position to abstract portions of it, either for consumption in their own families or to be retailed among their humble neighbours. At Clerkenwell upon the same day Ebenezer Durman, a grocer of Whitecross-street, St. Luke's, was summoned by the St. Luke's Vestry for having deposited for the purposes of sale 135 tins of salmon, 211 tins of condensed milk, 235 tins of sardines, 15 tins of corned beef, three jars of pickles, 5 lb. of figs, 78¼ lb. of dates, and 14½ lb. of prunes, which were unsound and unfit for human consumption. Sanitary Inspector Adams proved seizing the goods in the defendant's store cellar. He at first denied having any "blown" tins but afterwards said that they must have been overlooked. The defence was that the stuff was a collection made by the last tenant from whom the defendant had bought the business, and that the milk had been bought from a broker so that the defendant had to run risks of this sort. (It is curious to note how unfortunate persons of the defendant's stamp are in their business relations) The magistrate was most unsympathetic and fined the defendant £50.

LONDON STREETS AND THE VESTRIES.

MANY of the inhabitants of London suffered a considerable amount of personal inconvenience from the slight fall of snow which took place on Friday, Feb. 2nd. Formerly it was the duty of every householder to remove the snow from the pavement in front of his own house, and as a general rule the work was quickly and thoroughly carried out At that time people who were needy and out of work promptly tried to make bargains with the various householders to do the work in return for some small amount of ready money Under the provisions of the Public Health (London) Act of 1891[1] the duty of cleansing the pavements as well as the streets devolved on the vestries. It is extremely discreditable to some of these bodies that they should show so much apathy in carrying out the statutory duties committed to them. In some parts of London the snow was removed from the pavements on Saturday, the morning following the snowstorm, but in some parts—for example, in many streets in Kensington—the snow was still lying thickly on the pavements in the afternoon of Sunday, and the vestries were apparently taking no steps whatever to get rid of the nuisance. It is a matter of common knowledge that it is an unwholesome and frequently a dangerous thing for people to spend a prolonged time with their feet wet, and it is to be feared that not a few of those who attended places of worship on Sunday must have sat for hours not only in discomfort but in peril of the maladies, not all of them trivial, in the causation of which wet feet play a part. It is impossible to suppose that the vestries of London would have any real difficulty in making arrangements for having the snow cleared from all the pavements under their charge in a very short space of time. Such arrangements must, of course, be made in advance, and we commend the question to the important bodies who have resting on their shoulders the care of the health of the people of London. Many local authorities appear to have a great desire to have the sphere of their labours enlarged, but if they will first carry out thoroughly the duties committed to their charge they can ask for greater responsibilities with more confidence.

THE HIGHER STAGES OF SEXUAL EVOLUTION.

DR. CHARLES FÉRÉ of Paris, who has given us much valuable information on the subject of the physiology and pathology of the emotions, has published an article[1] dealing with the sexual instinct in its higher phases which must command attention His paper is an argument for the repression of the brutal instincts in man and an insistence that they should not, even in the relations of marital life, play too naked and unrestrained a part and thereby afford a cause for danger to the sexual life. He points out that this danger is more likely to influence the sexual life of the woman owing to her relative ignorance and passivity. The common and, in Dr. Féré's opinion, widespread teaching that sexual indulgence is a necessity, a *sine quâ non* of healthy life, is not accepted as sound doctrine. Indeed, Dr. Féré goes so far as to assert and to adduce proofs to the effect that such teaching is mischievous; that the sexual instinct is not inborn but is acquired mainly through precept and example; and that the instinct which is at present being perfected and perpetuated by evolution is the parental instinct. A review of facts in the life-history of the lower organisms serves to show that among them the male (or less frequently the female) dies after the accomplishment of the sexual act. This shows the irresistible strength of the sexual impulse and demonstrates the potency of the instinct of propagation. At a higher stage of evolution we meet with those phases of sexual life and conduct in many birds and mammals in which a more restricted and restrained manifestation of sexual acts and needs constitutes a notable feature. In savages there appears what is practically a new phenomenon—viz, the practice of infanticide which is followed in order to avoid the natural consequences of sexual indulgence. A further departure from the normal is seen when sexual gratification is regarded both as a means and an end in itself and abortion is resorted to in order to avoid the responsibilities of marriage. Thi last phenomenon bears within itself a peculiarly pernicio element, a mode of thought and feeling which is fatal to th best instincts of the race. Dr. Féré touches upon th gravity of this aspect of the problem and the profoun weakness which it is likely to entail on nations among wh fœticide is prevalent. He enjoins the wisdom and healthfulness of sexual chastity and temperance in both marital and extra-marital life, and points out the benefits resulting from the begetting of a moderate number of children who will be able to receive the advantages of education and of high ideals, which are denied to those whose parents are handicapped by the excessive cares and anxieties of too large families. Dr. Féré concludes by expressing a strong opinion that this is the aim and ideal to be striven after in the present stage of our sexual evolution.

A TESTIMONIAL TO DR. NEALE OF THE "DIGEST."

WE publish in another column an appeal signed by leading members of our profession on behalf of an object which we are sure will meet with the universal approval of our medical brethren. The suggestion is that Dr. Neale, the compiler of the well-known and invaluable "Digest," should be presented with a testimonial "as a recognition by his professional brethren of his long-continued and invaluable labours on their behalf." To ourselves as medical journalists the value of the "Medical Digest" is incalculable, and we take it that every medical man writing upon any professional subject refers to the same work to find out what has been said upon his subject previously. Dr. Neale has spared neither time nor money in the prosecution of his work, and we most earnestly hope that his colleagues in the profession will show their sense of his unselfish toil upon their behalf.

THE BATLEY TYPHOID OUTBREAK.

AT the quarterly meeting of the Batley Town Council on Thursday last serious complaints were made against the Sanitary Committee regarding an outbreak of typhoid fever which has recently occurred in Batley and which some members of the council believe to be connected with a certain milk-supply. The proceedings of the council as reported in the local newspaper are not particularly instructive reading, but they serve to exemplify the inability of the average municipal mind to grasp the true bearing of medical problems. Alderman Nettleton, after reading an extract from the report of the medical officer of health, which, however, contained no reference to the subject, is said to have remarked that recently there had been a "scare" in the town respecting an outbreak of typhoid fever. That the outbreak was discovered before it had become widely diffused appears to have been entirely due to the prompt notification of first cases by medical men in the town, and for this we should have thought the council would have acknowledged their indebtedness to the profession. The worthy alderman, however, thought differently. "All the doctors in the town," Mr. Nettleton is reported by a local newspaper to have said, "were doing their best to detect cases of zymotic disease, but at the same time he was rather afraid that some of them were rather too anxious to notify them. If the doctors would only allow the suspected cases to remain a few days longer at home some would, he thought, turn out to be cases of another character." In the best interests of the people of Batley we sincerely hope that the opinion above expressed is not generally shared by the members of the Sanitary Committee. It should be remembered that the diagnosis of typhoid fever, in its early stages at any rate, is exceptionally difficult, and for this reason every encouragement should be given to medical men to notify promptly, so that suitable measures may be taken to isolate first cases, and thus to check the spread of the disease at the outset. If the first few cases are allowed to remain undetected it is impossible to estimate the mischief that may eventually accrue; and we are appalled to think that an alderman of the council, albeit on the very eve of his appointment as governor to a great educational institution in the town, could be found to advocate a proceeding which, if carried into effect, would be fraught with serious danger to the community. We regret to add that, according to the *Batley Reporter*, Mr. Nettleton in a subsequent speech thought it becoming to remark that "the typhoid epidemic was simply a scare which had been raised by some of the gentlemen in the medical profession." We are sure that on reflection the alderman will recognise with us the injustice of this aspersion, and we trust that he will take an early opportunity of apologising to the medical gentlemen of the neighbourhood, who seem to have acted skilfully and promptly for the preservation of the public health of Batley.

COCKLE-BORNE ENTERIC FEVER.

A LETTER *from the ex-Lord Mayor of Belfast* upon a subject of the deepest interest will be found on p. 421. The diffusion of enteric fever by means of oysters, cockles, and other shell-fish has often been the subject of comment in our columns and in our issue of Oct. 21st, 1899 (p 1109), the matter was discussed with reference to an outbreak of enteric fever at Exeter, the source of which was virtually traced to the consumption of raw cockles. We referred to the difficulties incident upon the attempt to get any Bill dealing sufficiently with this subject through Parliament. While waiting for this desired result we can only reiterate our former advice that people must be careful as to the source from whence they procure cockles, and in case of the slightest suspicion we would strongly advise them not to eat these dainties unless previously boiled. It is important also to point out that the question has been raised as to whether the several processes by which cockles are "boiled" or "cooked" are sufficient to destroy pathogenic bacilli present between the valves of these molluscs, and we have reason to believe that this matter is at the present time engaging the attention of the Medical Department of the Local Government Board.

PRECOCIOUS DEMENTIA.

DR. CHRISTIAN of Charenton has contributed to the *Annales Médico-Psychologiques* for 1699 a series of articles on this subject which are well worth reading. His study comprises the clinical and life histories of 35 cases, and includes a valuable historical account. He points out that both Pinel and Esquirol regarded this affection as a form of idiocy, and that it was reserved for Morel of Belgium to show its precise significance. More recent authors have named this disease hebephrenia or dementia præcox. Dr. Christian states that this affection is much more frequent than is usually supposed, and that he has met with 100 cases of it during 19 years. The characteristic symptoms are as follows: its appearance at the period of puberty, the variable delusions at the onset and in the early stage, the constant and sudden impulses, and the rapid termination of the attack by a condition of mental weakness more or less pronounced. Three periods exist—viz., the period of incubation, the period of delusions and confusion, and the period of mental enfeeblement (terminal period). Prodromal symptoms may be absent or may show themselves in a vague form, such as fatigue or inaptitude for work. Later there appears with more or less suddenness the mental disease in its characteristic form—e g., maniacal excitement, melancholia, mental confusion, or delusions of a hallucinatory or hypochondriacal nature. The patient passes now into the third stage, and it is remarkable how quickly this may attain its culminating point. Certain hebephreniacs remain on the borders of imbecility, others fall almost from the beginning into a condition of profound stupidity. In the lighter forms of hebephrenia the patient may exhibit only a slight mental enfeeblement which does not prevent his fulfilling the duties of ordinary social life. In the graver forms a more profound mental involvement persists and the patient passes into cataleptic and catatonic conditions and is liable to suffer from impulses. The differential diagnosis from acute mental confusion, from stupor, and from epileptic or alcoholic insanity is very difficult at the onset. The disease makes its appearance between the ages of 15 and 25 years. Dr. Christian does not accept or admit the almost exclusive influence of heredity or of degeneration which so many authors invoke as the main causal factor. He accords the position of first importance to debilitating causes, above all to over-exertion (*surmenage*), and contends that though the affection is at present relatively rarer in the female than in the male this disparity is already tending to disappear. He looks upon puberty as a contributory condition which facilitates the production of the disease.

THE BUCKLAND FISH MUSEUM.

IN our issue of Jan. 21st, 1899, we commented upon the fact that a select committee had recommended that this museum should be abolished and that many fishery boards and prominent fishermen had prepared a memorial to the Lord President of the Council and the President of the Board of Trade protesting against such a decision. On Feb. 5th the two Ministers concerned received a deputation who presented the memorial. The memorial called to mind the inception of the museum by the late Frank Buckland and asked for the maintenance and exhibition of the museum as being an institution in the interests of the sea and river fisheries of the United Kingdom. The reply was of the usual stereotyped official order. The Duke of Devonshire said that it appeared to him that the matter was one which more concerned the Board of Trade than the Education Department, and the President of the Board of Trade said that his department could not move in the matter without the assistance of the Treasury. He hoped, however, that the result of the deputation might be a careful inquiry into all matters connected with the museum and that they might be able to come to some conclusions satisfactory to the deputation and to all interested in the culture of fish. So the matter stands for the present, but it is obvious that something should be done to preserve the museum as a step towards using properly the unrivalled resources of the British sea and river fisheries as food for the people.

PHYSICAL TRAINING IN SCHOOLS.

A CIRCULAR has been issued by the Scottish Education Department to school boards and managers of schools upon the importance of physical exercise and military drill being taught in such schools. The circular says:—

> Lord Balfour is convinced that such exercises, apart from any other consideration, would be a most important aid in attaining some substantial objects at which all education must aim. Not only do they tend to improve manual dexterity and to render more alert the faculties of observation, but they are also pre-eminently useful in developing those habits of comradeship, of responsibility, and of individual resource which are of supreme importance, not only to the nation as a whole, but to the individual pupil. Indirectly they bring the individual into contact with the principles which lie at the foundation of national defence, and they bring home to him his duties and responsibilities as a citizen of the Empire, while at the same time giving him an opportunity of strengthening and developing his physical powers and rendering him more fit for his ordinary employment. Whatever form the military service of our country may hereafter assume it is evident that the strength and security of the Empire as a whole as well as that of every individual citizen depend upon the extent to which the moral elements of and readiness of judgment, along with be developed. Success in this can only be achieved by careful consideration of the best methods and by employing these strenuously and zealously during school life. Attention to physical training becomes all the more urgent owing to the tendency of population to gather to the larger towns, where the opportunities for physical exercises are necessarily restricted.

These are weighty words and absolutely true. There is nothing which is so likely to develop habits of honesty, independence in action, and at the same time unselfishness as the usual forms of physical exercise. A man must not play for his own hand if he wishes to win a game at football or cricket, and to be a unit in a corps is an object-lesson for an egotist. This is the training which far more than book learning is the strength of our public-school education, and similarly the want of it is the defect in most elementary schools. The circular goes on to say that enormous good might be done by the formation of cadet corps among those who have just left school, which corps would be arranged for by the school managers in combination with local associations of public spirited inhabitants. In seaboard parishes nautical training should be developed. We wish the movement every success for we are convinced that it proceeds upon the right lines.

INTERNATIONAL CONGRESS OF MEDICINE, PARIS, AUGUST, 1900.

THE Paris executive of the International Medical Congress have issued a notice to the effect that at the request of the French Society of Electrotherapy and Radiology, the Inter national Congress of Medical Electrology and Radiology to be held in connexion with the International Congress 1900. A commission composed of M. Weiss, professor of th University of Paris, President; MM. Apostoli and Oudin, Vi Presidents; M. Doumer, professor at the University of Lil general secretary; M. Meutier, secretary; M. Boisseau du Rocher, treasurer; and M. Bergonie, professor at the University of Bordeaux, M. Bouchacourt, M. Branly, professor of the Catholic Institute of Paris, and other distinguished medica men in Paris have been asked to assure its organisation This Congress will take place in Paris from July 27th August 1st, 1900. All inquiries for further informati should be forwarded to Professor E. Doumer, gene secretary, 57, Rue Nicolas Leblanc, Lille. Notices of int tion to join the Congress are to be sent to Dr. Meuti 11, Rue de Miromesnil, Paris.

TUMOURS OF THE CAUDA EQUINA.

DR. B. SACHS[1] records two cases of tumour pre upon the cauda equina successfully located by diag and removed by operation. Case 1 was that of a aged 56 years, who had suffered for 18 months severe pain in the right thigh and leg and subseq had sudden severe cramps of the muscles of the thig had been previously wounded by a bullet in th War, the missile passing obliquely through the up of both thighs. The pains from which he now were suspected to arise from the old wounds cause bullet and anti-neuralgic treatment was tried but success. The muscles of the limbs were somewha but whether this could be attributed to the prese (of the cauda equina) or to the old bullet injury years previously was not certain. The spinal c sensitive to pressure along its length and deep pr the spinous processes of the second and third lu bræ produced some pain. Light pressure at a s inch to the left of these vertebræ gave rise to p and darting down the lower limb exactly experienced at other times. The left k normal but the right was absent. There ankle-clonus nor tendo Achillis jerk. The cremasteric reflex was greatly increased on the left side, but all other reflexes (superficial and deep) appeared to be normal. The vesical and anal reflexes were present and unimpaired. The diagnosis of a new growth was rendered probable by the assemblage of symptoms and, owing to the absence of rectal and vesical disturbance and by reason of the unilateral character of the symptoms, the lesion was regarded as affecting the cauda equina rather than the lumbar part of the spinal cord itself. Operation (laminectomy) was performed by Dr. Wyeth, and on dissecting away the muscles from the median line from the third lumbar vertebra upwards, a bulging tumour was observed on the left side of the cauda between the levels of the second and third lumbar vertebræ. The growth was adherent to the dura mater and to the bones, but it was separated and removed without injury to the spinal nerves. The patient made an excellent recovery and was free from pain, cramps, and all other distressing symptoms, and was able to walk with comfort. Microscopic examination showed the growth to be an alveolar sarcoma. Case 2 was that of a man, aged 32 years, who had suffered from shooting pains in the back and legs for a year. The pains increased in frequency and severity and muscular power was diminished in both lower extremities, the left leg being the weaker, while locomotion was difficult. The knee-jerks were absent and the right plantar reflex was abolished. The tendo Achillis reflexes were wanting on both sides. Sensation appeared to be normal except for a distinct diminution of sensation on the dorsal aspect of the left thigh and the left half of the perineum, scrotum, and penis. The vesical and rectal reflexes were rather weak. The pupils were equal and reacted normally. At first tabes dorsalis was suspected, but treatment by suspension and by the iodides produced no improvement. The slow progress and localisation of the symptoms pointed to an involvement of the lower portion of the spinal axis of markedly unilateral character. Laminectomy was performed by Dr. Gerster at the second and third lumbar vertebræ. A soft gelatinous elastic tumour, pale and nodular, was found to be compressing the cauda equina between the second and fourth lumbar vertebræ. This was removed and the patient made a good recovery. Microscopic examination showed the growth to be a fibro-sarcoma.

A COUNTY INEBRIATES ACT BOARD.

A CONFERENCE was held recently in the County Hall, Preston, of representatives of the county council, county boroughs, and non-county boroughs of Lancashire for the purpose of promoting a Bill in the present session of Parliament to constitute an Inebriates Act Board for the County Palatine of Lancaster and for other purposes. The Right Hon J. T. Hibbert presided and there was a large attendance. The chairman explained the importance of the subject and expressed the opinion that the movement should be put on a firm and satisfactory basis He regretted that they had lost so much time in dealing with the subject. The town of Oldham had not seen its way to join this combination, and unless Oldham were ready and willing to establish a home of its own the town would be lacking in a very important duty towards its citizens, for no one would believe that a manufacturing town of such a size was without its inebriates who require efficient and judicious treatment. It was announced that Mr. Clare, the newly appointed clerk to the Lancashire County Council and formerly the town clerk of Liverpool, had drafted a Bill to be promoted in the present session of Parliament by the County Council to authorise the formation of a joint board. The conference considered the clauses in detail. The preamble of the Bill, which was adopted, stated that under Section 9 of the Inebriates Act, 1898, the council of any county or borough were empowered to contribute towards, or to undertake themselves, the establishment or maintenance of an inebriate reformatory, and to combine with another council or councils for any such purpose. Any borough or county council might contribute towards the establishment or maintenance of a retreat, and two or more might combine. There is no doubt that this is a wise and important step towards the carrying out of the Inebriates Act of 1898, and it is to be hoped that other public bodies will follow the example of this combination in Lancashire, for it is only by such combinations being formed that efficient and satisfactory reformatories can be established.

STREET NOISES.

ON Feb. 6th the London County Council passed the following by-law: "No person shall for the purpose of hawking, selling or advertising any newspaper call or shout in any street so as to cause annoyance to the inhabitants of the neighbourhood." The penalty provided is a fine of 40*s*. We congratulate the Council most warmly upon having taken this step. The nuisance caused by, for example, newspaper yellers is unendurable. As we have said over and over again, there are hundreds of newspaper sellers who do not shout and who make a living; and Mr. Frank Smith, who is reported as saying that the new by-law would take away the living of hundreds of men and boys, is suffering from perfectly groundless fears. The continual howling of "Winner" is bad enough, but this is as nothing compared to the bellowing of "Awful slaughter" or "Great British victory" to which we have been nightly subjected since the war began. We believe the law will not come into operation for some days, but we hope that when the period of grace has expired the police will see to it that it does not remain a dead letter.

AUGUSTE COMTE: A STUDY IN MENTAL PATHOLOGY.

DR. W. W. IRELAND contributes to the pages of the *Journal of Mental Science* (January, 1900) an interesting study and critique devoted to the mental life and history of Auguste Comte. The mental aberrations of that philosopher were previously made known by his friend and biographer, M. Littré, and more recently by Dr. G. Dumas in three articles filling 87 pages of the *Revue Philosophique* (vol. xlv., 1898). Comte was of delicate health and suffered from a weak digestion in youth. At the age of 27 years he married Caroline Massin, a lady subsequently known to have been a person of loose morals, and their domestic life was far from happy. She ultimately quitted his house to live with a lover. Dumas tells us that Comte's wife deceived him, was unfaithful to him, "and made his home-life hard and jangling." Domestic and wordly troubles conspired to bring about a breakdown in the philosopher's mental health. "I have often conceived thoughts of suicide," he subsequently wrote, "and should have probably yielded to them had the bitterness of my domestic life not been neutralised by the increasing consciousness of my social mission." Twice he made attempts to drown himself but was rescued. He plunged into excessive mental work and signed his register of marriage with the words "Brutus Bonaparte" appended to his name. For two years, while suffering from melancholia with suicidal impulses, he was under the treatment of the famous mental physician Esquirol. He suffered much from sleeplessness, irritability of temper, and repeatedly from "nervous crises," one of which occurred in 1838, another in 1842, and a third in 1845. Two years after his separation from his wife he met and conceived a violent

me Clotilde de Vaux. His affection was
, after a brief courtship the lady died a
mption. In a letter to Madame Comte,
had been separated some time, he recounts
this lady who had become "his eternal
his veritable spouse." "This attachment,"
reland, "had brought out the affective and

THE MEDICAL CHARITIES OF MANCHESTER.

A PAPER recently read before the Manchester Statistical Society by Mr. F. Brocklehurst gives some interesting details as to the charitable institutions dispensing medical aid which exist in Manchester and its suburbs. The paper was written upon details supplied by the report of the local Hospital Saturday and Sunday Funds, and in all 20 medical charities were considered. Mr. Brocklehurst pointed out that the information contained in the various reports is "of an uncertain and perplexing character. Few of them give any idea of the number of beds contained therein and fewer still of the cost per patient treated. Their methods of bookkeeping are as varied as their auditors." Mr. Brocklehurst, however, wished it to be understood that in referring to "irregularities" he did not mean in the least to suggest that the accounts were kept in anything but the most scrupulously honest fashion. The grand total of patients amounted to 217,527, but allowing for double and treble entries Mr. Brocklehurst considered that a total of 150,000 patients was annually dealt with. Only six or possibly seven of the charities give any information as to where the patients come from. Financially many of the institutions carry on their work "while standing on the verge of chronic insolvency." It is satisfactory to find that Mr. Brocklehurst came to the conclusion that instances of hospital abuse were very few and far between. Two evils, however, were very apparent and these were the amount of overlapping and waste of time of the medical men. For the former evil he suggested that the chronic cases might well be transferred to the provident dispensaries. For the latter evil he referred to the scheme put forward by himself some two years ago of a medical clearing house.[1] He asked if it were "not possible to establish in the centre of Manchester a receiving house and an out-patients' department from which, as from a centre, cases of sickness could be transferred to the special hospital provided for them." Such lan, says our special correspondent in Manchester, might be feasible in Manchester and would be well But its execution would entail something of the nature of a central hospital board, and such a board even in an embryo condition would probably be the cause of heart-burning and jealousy among the various tions. Many hospitals, to say nothing of other charitable institutions, live firstly by appeals *ad misericordiam* in which they give details of crushing loads of debt and, secondly, by putting forward lists of the number of persons benefited. The more numerous this first list is the more worthy is the charity in the eyes of the unthinking almsgiver. These two incentives to irresponsible giving would probably be done away with by the carrying out of Mr. Brocklehurst's scheme; and in whatever town it was adopted some of the smaller charities would disappear. Probably in the end this would be a good thing, but the process of extinction would be by no means painless and might do harm.

FURTHER EXPERIMENTAL EVIDENCE REGARDING THE VALUE OF TUBERCULIN AS A TEST FOR TUBERCULOSIS.

THE Technical Instruction Committee of the Cheshire County Council have recently carried out a most important series of experiments with tuberculin, their object being to form a decision for themselves upon the following points: 1. To test the reliability or otherwise of tuberculin as a means of diagnosis for tuberculosis in cattle. 2. To see in what percentage the milk of those reacting contained tubercle bacilli. 3. To estimate the direct loss that would be incurred by a farmer in clearing his herd of all infected animals. 4. To see if the appearance and manipulation of the udder could be relied upon as indicating the presence of tuberculous milk. 5. To observe the effect of regular and systematic injections of tuberculin particularly in regard to the future reactions and as to whether any curative property was shown; also as to whether the injection of tuberculin would propagate the disease in animals not already tuberculous. The testing was done by Mr. Laithwood, F.R.C.V.S., chief veterinary inspector to the county of Cheshire, the post-mortem examinations being made by the same gentleman assisted by Mr. King, chief veterinary inspector to the corporation of Manchester, and Mr. Storrar, veterinary inspector to the city of Chester. Professor Delépine of Owens College undertook the microscopical examination and analyses of the milk of all reacting animals and of portions of the carcase where doubt existed. Two herds, one at the Dair Institute, Worleston, consisting of 52 cows and two pedigree shorthorn bulls, and the other at the Agricultural School, Holmes Chapel, consisting of 16 cows and one pedigree shorthorn bull (two years and nine months old), were tested. The tuberculin was prepared by Professor McFadyean of the Royal Veterinary College. As the result 50 animals were declared free from tuberculosis, 17 were declared infected, and four doubtful. The udders of those that reacted were carefully examined, only one being found indurated; examinations of the milk of these were made by Professor Delépine and tubercle bacilli were detected in one instance only. Two out of the three bulls were found to be tuberculous the oldest one being badly affected. 10 of the animals were slaughtered the result i every case verifying the conclusions drawn from the reac tion. Nine cows were isolated and submitted to repeated injections of tuberculin at certain intervals, the cattle being afterwards slaughtered and examined. With reference to these the conclusion arrived at was "that continuous injections of tuberculin at short periods of time will cause reaction to cease in an animal that has previously been shown to be tub ..." It was pointed out that on this account tuberculin might be put to dishonest uses and that therefore stringent restrictions ought to be placed upon its sale, only duly accredited persons being allowed to purchase it As regards the "curative' property of tuberculin it was considered that none of the experiments gave encouraging evidence Although the experiments traversed ground which is now fairly well trodden they are of great value in confirming what has already been done to prove the diagnostic reliability of tuberculin and in bringing the position of modern knowledge under the eyes of the Cheshire agricultural community

---

THE MEDICAL DIRECTORY THE DISTRIBUTION OF THE MEDICAL PROFESSION

THE *Medical Directory* for the year 1900 has just appeared, the issue of this invaluable work of reference having been delayed on account of a fire which occurred at the printers establishment towards the end of last year The total number of practitioners for 1900 is 35,651, an increase of 657 over the total for 1899, which was 34,994 This, at least, was the total given in the 1899 edition although in the tabulated statement published in the 1900 edition the total for 1899 is given as 35,117, and hence the increase for 1900 is only 534, but the discrepancy probably arises from the taking in of those qualified during 1899 Continuing the comparison of figures for the two years 1899 and 1900 and taking as our authority the tables in the 1899 and 1900 edition it is possible that decentralisation is proceeding This is a movement which has long been prophesied as about to happen, and it may have begun though the figures are not conclusive The figures for London in 1899 were 6117, in 1900 they are 6102 Provincial England for 1899 showed 15,497, in 1900 the figures are 15 794 For Wales the figures in 1899 were 1100, in 1900 they rise to 1127 Scotland in 1899 had 3394 practitioners and in 1900 has 3462 Ireland in 1899 possessed 2551 and in 1900 the figure is 2559 Practitioners living abroad in 1899 numbered 3795 and in 1900 their total is 3675 The services in 1899 mustered 2528 medical members and in 1900 the list rises to 2705 The "too late list for 1899 numbered 12, and in 1900 rises to 27 We are glad to see that an alphabetical arrangement has been adopted for the list of the hospitals

TUMOUR OF THE PITUITARY GLAND

S PECHKRANZ[1] contributes a paper on the above and gives an account of clinical observations made throughout the history of the case from the first onset of symptoms two and a half years before death The patient, a young man, aged 27 years, suffered at first from troubles which were supposed to be of renal origin and of a uræmic nature but the absence of œdema and of urinary indications negatived this view Both syphilis and tuberculosis could also be excluded He suffered from headache, and this was followed by troubles of vision in the course of which one eye became completely blind while the other was simultaneously affected with hemianopsia At a slightly later stage there developed a double optic atrophy The two oculo motor nerves were next attacked and an almost complete ophthalmoplegia (internal and external) followed There was no involvement of any other sense and there was complete freedom from localised paralysis or convulsions A diagnosis of neoplasm at the base of the brain affecting the optic chiasma was made The necropsy revealed the following conditions The pituitary gland was replaced by a large tumour, no part of which was adherent except to a spot at the back of the sella turcica The tumour was composed of three parts, the chief of which occupied the sella Prolongations from this passed forwards into the orbital cavities and its dorsal part projected into the third ventricle between the cerebral peduncles Small nodules of growth were situated around the margins of the tumour and the whole mass was encapsuled in a tough membrane like the dura mater There was no remnant of the pituitary gland The tumour was a sarcoma The cerebral substance in contact with its margins showed a slight degree of local softening and a portion of the neoplasm itself had undergone softening as the result of a hyaline degeneration of its vessels In the course of its growth forwards it involved the optic chiasma slightly, more on one side than the other, hence the amaurosis on the one side, combined with hemianopsia on the other side As the growth continued to increase the involvement of the other optic nerve was complete and hence total blindness resulted It is interesting to record that the patient showed a moderate degree of hypertrophy of the feet and hands and of the face, the augmentation of volume in these organs producing an appearance like that of acromegaly The enlargement was practically limited to the soft parts the bones apparently not suffering enlargement The patient had a feminine type of skeleton and the sexual organs showed insufficient development (hypoplasia) Pechkranz thinks that the patient had a congenital anomaly in the structure of his pituitary body and regards the condition of the skeleton, of the sexual organs, and finally of the hands face and feet as associated with the abnormal condition and eventual destruction of the pituitary body.

THE VALUE OF BACTERIOLOGICAL EXAMINATIONS TO THE COMMUNITY

AT the last meeting of the Lambeth Vestry on Thursday night the medical officer of health, Dr Joseph Priestley, presented a report made to the Sanitary Committee showing the result of the first year s working of the bacteriological laboratory recently established by the vestry Bacteriological outfits were supplied to medical practitioners in the parish and examinations made free of charge A total of 388 examinations were made during the year 214 examinations were made in suspected cases of diphtheria, the true diphtheria germs were found in 99 In 81 cases of suspected typhoid fever, 43 gave the Widal or typhoid reaction That is to say that bacteriology determined the diagnosis in 46 per cent of suspected cases of diphtheria and 53 per cent of suspected cases of typhoid fever Dr Priestley in his report concluded that there was thus a saving in notification fees sufficient to justify the provision of the bacteriological laboratory

SPLENIC ANÆMIA COMPLICATED BY DIABETES MELLITUS

IN the *Journal of the American Medical Association*, Dec 30th, 1899, Dr H A Hare has published a case of splenic anæmia complicated by diabetes mellitus which appears to be the only one on record Splenic anæmia is still a comparatively new disease and only a limited number of cases have been recorded[1] so that it is impossible to say whether this association is common or not Whether in the case in question there was any connexion between the two conditions Dr Hare cannot state The patient was a man, aged 24 years who was admitted to hospital in 1895 He complained that in July he had begun to suffer from severe pain beneath the left clavicle which extended downwards into the left hypochondrium He was exceedingly pale, his conjunctivæ were yellow and his spleen was enormous There were hæmorrhages into both retinæ In the blood there was a great excess of lymphocytes, but the total number of leucocytes was about normal. For a period of two years the leucocytes varied from 8000 to 4000, usually averaging about 6000. In December the lymphocytes were 84 per cent., mononuclear cells 4, polynuclear 8, and eosinophiles 3. The red corpuscles varied from 1,000,000 to 2,800,000. In February, 1898, attacks of epistaxis began; the temperature and urine were normal, the hæmoglobin was 40 per cent., the red corpuscles 1,620,000, and the white corpuscles 7000. At the beginning of November polyuria suddenly began; he passed 10 quarts of urine in the 24 hours, containing 30 grains of sugar to the ounce. Previously to this attack he was gaining weight and working in a barber's shop where he was on his feet from 7 A.M. to 9 P.M. He improved under rest, good food, and large doses of arsenic.

[1] Neurologisches Centralblatt No. 18, 1899

[1] THE LANCET Jan. 13th, 1900, p. 118

ON Saturday, Feb. 3rd, the county council of Salop elected Mr. Charles Porter, M.D. R.U.I., Barrister-at-law, to succeed the late Dr. W. N. Thursfield as medical officer of health for the county. Dr. Porter brings to the duties of this important office an experience gained first in East Kent and latterly in the county borough of Stockport where he has initiated and carried through many and varied sanitary improvements. His vigorous action at Stockport, when the lay officials, both central and local, of the St. John Ambulance Association seemed unable to realise how much their Association depended upon the assistance of medical men, won the approval of all members of the profession.

THE death is announced of Mr. William Adams, the well-known orthopædic surgeon. Mr. Adams, who was specially noted for his interest in operation for the cure of deformities arising from ankylosis of the hip-joint, was consulting surgeon to the National Hospital for the Paralysed and Epileptic.

THE anniversary dinner of the Medical Society of London will be held in the Whitehall Rooms of the Hôtel Métropole on Thursday, March 8th, at 7 P.M. Communications should be addressed to the honorary secretaries, Dr. James Calvert and Mr. F. C. Wallis, at 11, Chandos-street, W.

THE annual oration of the Hunterian Society will be delivered by Dr. F. J. Smith in the theatre of the London Institution, Finsbury-circus, on Feb. 14th at 8 30 P.M. The subject will be the Influence of Modern Medicine on Surgery. Members of the profession are invited to attend.

THE death is announced of Francis Charlewood Turner, M.A., M.D. Cantab., F.R.C P. Lond. Dr. Turner was physician to the London Hospital and consulting physician to the North Eastern Hospital for Children and the London Orphan Asylum.

IT is announced that the Prince of Wales has kindly consented to lay the foundation-stone of the new infirmary at Newcastle to be built in commemoration of Her Majesty's Jubilee. The ceremony will take place in June.

Dr. William Pasteur, assistant physician to the Middlesex Hospital, and dean of the Medical School has been elected physician to the hospital.

Mr. Reginald Macleod, C.B., has been appointed Registrar-General in the place of Sir Brydges Henniker, who has retired.

THE WAR IN SOUTH AFRICA.

AT the moment of writing there is little official news to indicate the movements of General Buller's force. The situation may perhaps be best described as one of hope not unmixed with anxiety on the part of the public, reticence on the part of Government, and, we fear, much futile, if not mischievous, action on the side of those who are animated by merely party spirit or are unworthily seeking an ephemeral notoriety by indulging in hostile and indiscriminate criticism. No doubt there have been miscalculations and blunders—an under-estimation of the extent of the rebellion and of the forces at its back, and an over-estimation of our own military power and prowess—some of which were avoidable, but this is not the time to go into all that. *The nation has now to look* to the present and the immediate future and to follow out stubbornly and with set purpose a definite line of action directed to a definite end. The country is, not for the first time in its history, face to face with a crisis of magnitude, and we feel confident that our present difficulties will be met with the same dignity and fortitude that have characterised the nation in the past. It is no new thing, after all, for forces acting on the defensive and occupying entrenched positions to offer a strong and formidable resistance. It was so in the Russo-Turkish war in the case of Plevna, in the Franco-German war, and, to cite examples nearer the present time, we may point to our own experience in the late tribal campaign on the North-Western frontier of India. If Sir Redvers Buller succeeds in the relief of Ladysmith the complexion of the war will change. A concentrated force will then be free to carry out the original strategical plan of the campaign. The news from General French on the Orange river and from General Hector Macdonald on the Kiet river is reassuring in the meantime, and reinforcements from all sides, it must be remembered, are pouring into South Africa, which reinforcements include a strong force of Royal Artillery, mounted infantry, and cavalry.

We are very glad to notice that the successful work done by the Royal Army Medical Corps during the present war was mentioned and duly recognised in the House of Commons during the late debate on the amendment to the Address. While on this subject we may say that we have only met with one discordant note in the praise accorded to the medical service by the press of this country. It had reference to Wynberg, and we have the best authority for stating that it was incorrect. Our readers have had the assurance, moreover, of Sir William MacCormac and subsequently of Lord Roberts that the military hospitals are in a highly satisfactory condition, and from all sides we have heard nothing but commendation of the medical arrangements. Recently we had an opportunity of seeing an extract from the letter of a staff officer at De Aar in which he alluded in terms of high commendation to a hospital train and its fittings. We are a little surprised that contradictions of the rumour to which we refer which have reached headquarters from authoritative sources have not been officially made public.

Netley Hospital is becoming full of patients from South Africa. It was visited the other day by a Royal party from Osborne and it has been intimated that Her Majesty will shortly inspect that institution and visit the wounded there. In the hospital at the present time there are about 800 patients, of whom 686 are from the front. Of these, 357 are sick and 329 wounded, whilst 279 cases have already been treated and discharged either on furlough or to go back to the front. There is still room for 300 patients. Special hospital huts are being erected at the rear of the central buildings which can accommodate 1000 extra patients. Arrangements have been made for the convalescents to leave Netley as soon as they are able, so that the hospital will be available for the wounded as they arrive.

The Royal Army Medical Corps has a grateful recollection of the service Lord Lansdowne rendered them in the past and a keen appreciation of the very liberal hospital arrangements provided for the sick and wounded in this campaign. It goes without saying that he has had an enormous amount of responsibility and labour in connexion with this war. His department has been very generally abused. We trust that none of our readers will be found among his too previous critics.

Sir William MacCormac continues his interesting notes this week.

HOSPITAL ACCOMMODATION FOR THE SICK AND WOUNDED FROM SOUTH AFRICA.

We give below the names of some of the larger hospitals, the governors of which have undertaken to provide accommodation for the sick and wounded from the seat of war. We also give the number of beds which each institution is able to place at the disposal of the War Office. This does not pretend to be a complete list and we shall be glad to hear from other institutions concerning their intentions. It should be pointed out that the omission of the name of any institution does not necessarily show any want of patriotism in that institution, the pressure on many of our large hospitals being so excessive that they are unable to find room for the ordinary applicants for beds. It would be of no national service whatever for such hospitals to make any attempt to help the War Office. Mr. Sydney Holland, the chairman of the London Hospital, explains in the letter which we publish on page 423 exactly the conditions under which the possible assistance of the hospitals has been sought; and while we feel confident that every medical institution in the country would, if it were necessary, be only too willing to provide beds for those who may be wounded or who may fall sick in the cause of their country, we trust that the numbers of our wounded and sick will not be so large as to outstrip the regular accommodation at Netley and the Herbert Hospitals.

Royal Orthopædic Hospital	10
London Temperance Hospital	10

The Central Hospital Council for London have been informed by the Director-General of the Army Medical Department that all patients arriving from South Africa will be first sent to Netley or to the Herbert Hospital, Woolwich, for assortment and for the regularisation of their papers, and they will be thence drafted as necessity arises to other hospitals. Any patients sent to the London hospitals will in all probability be drafted from Woolwich and will be, as regards quite nine-tenths of them, men who have come from the seat of war in South Africa. In no case will patients suffering from venereal or infectious diseases be sent. The patients will be under the entire charge of the hospital staff, and subject to the hospital rules, as in the case of ordinary patients, and they will be removed by the Government when required. Probably no beds in London hospitals will be needed for three months, and at least 14 days' notice of the patient's arrival will be given. The patients will embrace privates and non-commissioned and warrant officers. Ample provision has already been made for patients needing treatment in convalescent hospital and homes.

(NOTES FROM SIR WILLIAM MACCORMAC.)

(Continued from p. 336.)

WE arrived at Cape Town from Natal, a journey of 1000 miles, on Jan. 8th. People at home do not realise the immense distances here which occasion the greatest difficulty in prosecuting the war. On the 9th I visited the general hospitals at Wynberg and at Rondebosch, a few miles on this side of Wynberg, and also the Portland Hospital.

No. 1 General Hospital comprises all the hospital buildings at Wynberg and has been already described by me in my first letter.[1] I was consulted concerning many wounded officers, and inspected the wards which I found in excellent working order. 120 wounded officers have passed through the wards since the battles on the Modder river and at Colenso. The wounded are all very cheerful and are doing well. Several of them are to be sent home in a few days in the *Majestic*, these being principally cases unlikely to recover before the end of the war. No. 2 General Hospital consists entirely of tents. These have been pitched in a very suitable position, on dry, sandy soil, on the gentle slope of the hill near No. 1 General Hospital. It is made up of 99 double-fly marquees, each containing six spring beds, besides operating and store tents. All the tents are floored with boards, and there is an ample supply of easy chairs, flowers, and all the minor luxuries of a hospital. The total number of beds is 504, and there are the usual store, office, operating, and men's tents. About 350 cases are at present provided for in this hospital. The staff consists of five medical officers of the Royal Army Medical Corps, 12 civilian surgeons, and eight sisters of the Army Nursing Service. I here assisted at an operation and visited all the serious cases, giving my opinion where it was invited, as was often the case.

On leaving this hospital I proceeded by train a few miles nearer Cape Town to Rondebosch, where No. 3 General Hospital and the Portland Hospital are situated together on elevated ground, led up to by a road running through beautiful pine woods. No. 3 General Hospital is made up as follows:—There are 73 double marquees, each containing from four to seven beds, according to urgency; one marquee as an operating tent, this being preferred by the commanding officer to the ordinary small operating tent of the field hospital pattern; two tents for the use of patients before and after operation; a darkened tent for x-ray purposes; and six store tents. The process of erection of this hospital was begun on Dec. 9th, and it now presents a most neat and orderly appearance and is in full working order. The marquees are floored with wood and provided with first-class beds. Large pots of flowers have been placed between the tents and easy chairs abound in suitable situations beneath the trees for the convalescent patients. The situation is a charming one as regards natural beauty and makes a cheerful and invigorating spot for the healing of mind and body. The soil is a bright white sand and lovely pine trees and oak trees flourish amazingly. This whole hospital was, of course (as were also the other hospitals), erected by the men of the Royal Army Medical Corps. The detachment of this corps at this hospital numbers 96 non commissioned officers and men, who are under the command of Lieutenant-Colonel Wood, R.A.M.C., and Major Keogh, R.A.M.C.

The Portland Hospital, the generous gift of the Duke of Portland, is an admirable installation. It is under the military command of Surgeon-Major Kilkelly, Grenadier Guards, but he and two non-commissioned officers of the Royal Army Medical Corps are the only military elements connected with it. The staff consists of four civil surgeons (Mr. Bowlby and Mr. Wallace being at the head), four nurses, and 33 St. John Ambulance men. Captain J. F. Bagot, M.P., acts as secretary, and Lord Henry Cavendish Bentinck as treasurer. The hospital consists of 12 tortoise tents, each of which is capable of accommodating 10 patients if necessary. Each tent contains at present only six beds. These tortoise tents are very commodious and comfortable, but are not considered by some of the military medical authorities to be so suitable as marquees, on account of their lightness and the fact that they are not double. The

---

[1] This number would be increased should urgent necessity arise.

[2] 12 surgical, eight medical.

[3] As many as room can be found for when application is made.

[4] 18 of these beds are not entirely free of charge.

---

[1] Th

beds are comfortable spring beds of a convenient size and with good mattresses. The instruments and equipment were all bought privately from the best London firms, and there has been erected a special x-ray tent containing all the necessary equipment, including a dynamo. This hospital had only arrived three days before my visit, but, having the assistance of a detachment of the Royal Army Medical Corps from No. 3 General Hospital to erect the tents, the hospital was perfectly ready for the receipt of patients, and in fact a few wounded officers arrived almost at once.

On the 12th, by request of Lord Roberts, I accompanied that general and his staff during an official inspection of the Wynberg hospitals and the convalescent sanatorium situated at Claremont—a suburb about three miles from Wynberg. This sanatorium is built like a large hotel and has been employed for some time as a hydropathic establishment under a civilian medical practitioner. It is beautifully situated among pine trees. Half of the establishment has been hired by Government for the purpose of accommodating convalescent officers. This has been greatly appreciated by these sufferers, as it takes them away from the surroundings of the hospital proper where they have been treated, and from scenes of sickness and suffering, and enables them to enjoy more freedom and to associate with cheerful convalescents. At present there are 30 officers in this establishment for whom the Government is paying 10*s.* per diem per head. Each officer has a separate bedroom and there is a very spacious dining-room, a gymnasium, and, in fact, all the luxuries of a first-class establishment.

I also visited the hospital ship *Princess of Wales* which arrived a few days before from England. A description of this vessel would be superfluous, as that has already appeared before the ship left England. She has not yet received patients on board. Probably she will be sent on to Durban and embark sick and wounded at that port for home. Two German military attachés—Stabsarzt Dr. Schmidt and Stabsarzt Dr. Krumacher—have just returned to Cape Town from Modder river, where they have been working in the field under the medical officers of the brigade of Guards. They were present at the battle of Magersfontein and expressed great satisfaction and admiration of the medical work they witnessed there. It is worthy of note that these attachés from the German army are the only foreign military medical officers who have as yet made their appearance. Foreign Governments have all sent military attachés for tactical purposes, a fact which brings more prominently to notice the absence of the medical element. I do not remember that accredited medical attachés have been sent in any previous campaigns and it would appear to me an excellent example to follow in any subsequent one. A military medical attaché would probably see everything medical, which would not be the case were he attached to a foreign ambulance.

I add some brief notes of a few of the more remarkable cases at present in the base hospitals.

HEAD INJURIES.

CASE 1.—The patient was wounded on Dec. 15th by a Mauser bullet at a range of 600 yards or 700 yards. The entrance wound was immediately below the inner canthus of the left eye. The bullet passed through the spinal column in the upper dorsal region, emerging at the right post-superior iliac spine. The symptoms were a complete paralysis from the umbilicus downwards and a large patch of sloughing over the sacrum, and there was also cystitis. The patient has not improved since the injury although the wounds are healed, and he will die, as in any similar spine-fracture with lesion of the cord.

CASE 2.—The bullet in this case entered one and a half inches vertically above the external angular process of the frontal bone on the left side, emerging at the angle of the lower jaw on the right side. The same bullet then entered about the middle of the right clavicle, turned completely over, and lodged in the tissues above the clavicle. The bullet was removed after being skiagraphed. The bullet did not touch any bone. Loss of smell followed the wound, with œdema of the left lid and partial paralysis of the third nerve. At present the sense of smell has not returned and a central blackness in the field of vision has made its appearance. There is possibly a partial detachment of the retina.

CASE 3.—This patient had received a wound on Dec. 15th at a probable range of 800 yards. The entrance wound was at the junction of the malar bone and the zygoma on the right side. The bullet passed along the floor of the orbit and divided the right rectus muscle. The exit was through the lower lid of the left eye. The wounds at present have perfectly healed and there are no symptoms beyond upward strabismus which is very marked.

CASE 4.—The wound was received on Dec. 15th at a probable range of 500 yards. The entrance wound was through the left malar bone, and the exit wound was about one inch above, and slightly anterior to, the inferior angle of the scapula on the left side. The symptoms were complete paralysis of the left side of the body and the right arm (the right leg was not affected), pain on pressing over the seventh cervical vertebra, and difficulty in swallowing. There was no hæmoptysis. The paralysis is improving and there is no pain. Sensation first appeared, and then power of motion, in the right arm and then in the left arm and left leg. The other symptoms have also disappeared.

CASE 5.—The patient was wounded by a Mauser bullet which entered the left mastoid process near its apex. It passed across the hard palate, which it deeply grooved, and emerged through the right side of the upper lip, knocking away the incisor and premolar teeth on that side. The symptoms were deafness and facial paralysis, which set in at once on the receipt of the injury, but these have almost completely disappeared. There are no other symptoms and the wounds are healing.

In No. 1 General Hospital at Wynberg there have been up to the present time 24 cases of gunshot injury to the skull and three of the sufferers have died. No. 2 General Hospital shows a record of 16 cases, with two deaths.

WOUNDS OF THE THORAX.

CASE 1.—This was the case of a man wounded by a Mauser bullet on Jan. 1st at a range of 600 yards. The entrance wound was immediately below the acromial end of the left clavicle. The bullet passed on the inner side of the coracoid process, and the exit wound was an inch below the right acromion through the posterior fold of the axilla. The wound was received at 5 30 P.M., and after receiving it the man rode 200 yards and was then put into an ambulance. There had been slight hæmoptysis. He did not swallow any solid food until noon the next day, when the action of swallowing produced great pain over the manubrium sterni. This pain on swallowing persisted until the 8th. The pain on swallowing has now disappeared. There have been two severe attacks of dyspnœa with cyanosis since the 8th. The patient has severe pain in the cardiac region on coughing or on deep inspiration. The pulmonary physical signs were at first very obscure, but at present there are well-marked bubbling râles over both pulmonary bases with the addition on the left side of dulness on percussion, diminished respiratory murmur, and absence of vocal fremitus. The temperature is normal. In the supra-clavicular fossa on the left side there is a distinct swelling and a high-pitched systolic bruit can be heard immediately below the left clavicle. This bruit is also discoverable in a diminished degree on the right side. It is not conducted up the left carotid but down the left axillary artery. It is probable that injury has been done to the œsophagus, but probably not a penetrating wound, and there is possibly a traumatic aneurysm of the subclavian artery, but the evidence of this is by no means sufficient. The case is obscure.

CASE 2.—The patient was wounded by a shrapnel bullet on Dec. 12th. The bullet entered about the middle of the sulcus of the biceps muscle on the outer side of the left arm, and emerged at a corresponding point on the inside. It then entered the thorax in the fourth interspace at the posterior axillary border. The bullet was extracted from beneath the eleventh rib in the anterior axillary line and about one inch of the rib was resected. There was hæmothorax on admission. A pint of fluid blood was let out during the operation. There was no wound of the actual lung tissue. At present there is a slight cough, but otherwise no symptoms. The wound of operation is healing, and the other wounds have already healed.

CASE 3.—The patient received a wound from a Lee-Metford bullet at a close range of ten yards. The bullet entered the right sterno clavicular joint, making its exit about the middle of the spine of the left scapula. No symptoms occurred. The wounds healed by first intention, and the patient is now convalescent.

CASE 4.—The patient received a wound from a Mauser bullet on Dec. 15th at a range of 700 yards. The entrance wound was immediately to the right of the spine of the eleventh dorsal vertebra, and the exit wound was in the eighth intercostal space on the right side in the mid-axillary line. There was very severe hæmorrhage from the exit wound on receipt of the injury, and at present the physical signs indicate an effusion into the base of the right lung. Otherwise the patient is none the worse and the wounds have healed. The nature of the pulmonary effusion is unknown.

CASE 5.—This patient received a gunshot wound on Dec. 15th at a probable range of 700 yards. The entrance wound was an inch from the sternum over the second rib on the right side and the exit wound was an inch above the anterior superior iliac spine on the right side. Hæmoptysis, which has now ceased, was present for four days. There are no other symptoms except dyspnœa. The wounds have healed by first intention.

CASE 6.—The patient was wounded at Colenso on Dec. 15th at a range of about 600 yards. The entrance wound was at the posterior border of the sterno-mastoid muscle about its centre. The bullet has been located by the skiagram in the left claviculo-scapular region, the exact spot being as yet undeterminable. On entry there was marked numbness of the left hand, but this has now disappeared. There was also paralysis of the left deltoid muscle which still persists, so that he cannot elevate his arm at the shoulder-joint. There were no other symptoms, and the entrance wound healed at once.

CASE 7.—The patient received a wound from a Mauser bullet at a range of uncertain distance. The entrance wound was about the middle of the infra-spinous fossa of the right scapula, and the exit wound was at the outer edge of the right sterno-mastoid muscle about two inches above the clavicle. There was a certain amount of hæmoptysis at the time of the injury, but this has now disappeared. Swallowing was also difficult, but is now all right again. There is a very loud purring bruit over the right carotid artery, which is probably the seat of an arterio-venous aneurysm.

MISCELLANEOUS WOUNDS.

CASE 1.—A wound from a Mauser bullet was received on Jan. 2nd at an unknown range. The entrance wound was three inches directly below the inferior angle of the right scapula in the ninth intercostal space. The exit wound was about three quarters of an inch to the right of the xiphoid cartilage just below the seventh costal cartilage. The receipt of the wound was followed by a great deal of tympanites, vomiting, tenderness, and pain, but the patient is now doing well and the wounds have healed.

CASE 2.—In this case the entrance wound was half way between the left trochanter major and the posterior superior iliac spine on the left side, and the exit wound was in the outer part of the fold of the right buttock. There were no symptoms and the wounds have healed.

CASE 3.—This was a case of a bullet wound received on Jan. 4th at a range of about 600 yards. The entrance wound was two inches above the centre of Poupart's ligament and in a line from that ligament to the umbilicus. The exit wound was in the centre of the right buttock. There were no symptoms and the wounds have healed.

CASE 4.—In this case a Mauser bullet perforated the right tibia a little above its centre without causing complete fracture. The fibula was not broken. This case has progressed without interruption and the external wounds have healed.

CASE 5.—In this case a Mauser bullet traversed the right knee-joint beneath the patella, across the centre of that bone. The wounds have healed and the internal damage to the joint is apparently undergoing an uninterrupted recovery.

CASE 6.—The patient received a wound from a Mauser bullet at an unknown range, probably of the subscapular artery, the history being that a diffuse aneurysm was found in this region. Three weeks after the receipt of the injury the sac was laid open. The artery could not be located as it entered or left the cavity, so the axillary artery was tied in its first part. The patient is doing well.

CASE 7.—In this case the entrance wound was two and a half inches to the right of the second lumbar vertebra and the exit wound was below the ninth central cartilage on the right side. At first there were no symptoms, but the patient soon after the receipt of the injury became unconscious and hæmatemesis set in. There was also absence of abdominal breathing and tenderness over the hypochrondriac region. An iliac abscess is reported as having burst into the bowel and later pus passed for two days in large quantities. The patient is now doing well and no symptoms remain.

CASE 8.—The patient had received a bullet wound about a fortnight before at an unknown range. The entrance wound was one inch above the umbilicus in the median line. The exit wound was at the tip of the twelfth rib on the right side. The wounds have practically healed and there are no symptoms, although it was reported by Major Harris, R.A.M.C., of the field hospital at the front, that the omentum protruded after the injury was received, and that after replacing it he (Major Harris) had put his finger into the abdominal cavity.

CASE 9.—Field-Cornet Pretorius (a Boer prisoner) is lying in No. 1 General Hospital with an amputated thigh. I have previously mentioned this case. He received a bullet through his left knee on Oct. 21st. The bullet entered at the external side of the knee-joint and made its exit through the patella which was badly fractured. He made a remarkably good recovery from the injury, and was getting about on crutches, when, on Nov. 20th, he slipped and fell, refracturing the patella and bursting the cicatrix and skin open and causing a severe wound which suppurated. It then became necessary to amputate the thigh. The operation was successfully performed on Dec. 26th at the junction of the upper and middle thirds. The patient is now doing well.

It is very difficult to understand how some of these traversing wounds of the thorax have been so promptly and so easily recovered from. In the case of the abdominal injuries in some the visceral contents may have escaped perforation, but this can only be true of a few. In the others probably an empty alimentary tract and the rapid closing of the small perforations the bullet causes may account for the absence of any severe symptoms, but in some instances the nature and position of the wounds and the direction which the bullet has in every probability followed render recovery, practically either without symptoms or without any symptoms of importance, inexplicable.

WILLIAM MAC CORMAC.

(FROM OUR SPECIAL CORRESPONDENT AT THE BASE.)

Up to Jan. 17th the following operations have been performed in No. 1 General Hospital:—Amputations: of the arm, three; of the arm at the shoulder, two; of the forearm, one; of the thumb and fingers, four; of the thigh, six; and of the leg, six—total, 22. Excisions: of the elbow, one; of the ankle, two; and of part of the ulna, one. There have been 27 extractions of bullets, two cases of laparotomy, three sutures of nerves, and six cases of ligature of arteries. The patients in two cases of thigh amputation and in one case of laparotomy died.

We have had two or three trains down since I last wrote, but the cases were mostly medical and at the time of writing there are not many in hospital and we are sending a large number home in the *Majestic* to-morrow. Lord Roberts and Lord Kitchener visited the hospitals last week and were full of praise as respects the arrangements made for the wounded. I had not seen Lord Roberts for several years—the last time I met him being in India in 1892—but he is still the same courteous, kindly man that everyone knew him to be out in the East and he possesses a marvellous memory for faces. Lord Kitchener looked as fit as ever and seemed struck by the difference between the climate of Wynberg and that of Omdurman.

I hope that in the next great war we have in a decent climate so much money will not be spent on providing costly hospital ships, for although they are undoubtedly good in theory I cannot myself see where they come in in a war like the present when we have large and fast transports to convey sick and wounded to Netley. For this reason: the majority of patients who are sent home from this country are convalescent and do not require the elaborate arrangements which exist on board the hospital ships. The climate here is so good that there is absolutely no reason to send anyone to England till his wounds have practically healed. It must be understood that I am referring to hospital ships to convey wounded home and not of those engaged in bringing wounded from Natal. The latter ships, of course, should be as completely fitted as possible as the cases have to be treated on board. It is not as if we were fighting in a malarious or tropical country. From such a country it is absolutely necessary to clear patients out as quickly as possible, but here, where we have one of the finest climates in the world, I cannot myself see the necessity of equipping ships with exceedingly expensive fittings, operating rooms, and x-ray chambers, when the chances are that all the patients which they are likely to take home will have been convalescent some weeks before they embark. This, of course, is only my opinion, and I am quite open to correction on the matter. Given large, roomy, and fast transports, with no overcrowding, I am sure they would be found to answer better and would not be so expensive. Ask the authorities at Netley how many cases have arrived there which actually required hospital accommodation on board ship, excepting medical cases, and I think you will be surprised at the number. Far be it from me to cavil at the kindly thought and generous expenditure which have been shown in fitting out these floating hospitals, but still the fact remains that, given a good climate like that of South Africa at this time of year, their sphere of usefulness must be restricted to the conveyance of cases from coast ports to Cape Town for treatment at the base hospital, and not for the voyage to England.

The sanatorium at Claremont is proving a very useful adjunct to the various hospitals where officers are treated. Directly the patients are able to move about and do not require any elaborate dressings they are drafted to this charming place, where, surrounded by beautiful scenery and lovely gardens and looked after by a staff of nurses and medical attendants, they are soon fitted for duty again.

Wynberg, Jan. 17th.

THE HOSPITAL SHIP "NUBIA."

(FROM A DURBAN CORRESPONDENT.)

The conversion in Southampton of the steamship *Spartan* from an ordinary passenger-ship into a hospital ship, with accommodation for 130 patients, last October, elicited favourable comments from the home papers. However, in the fitting up in Durban of the transport *Nubia* for hospital purposes, with accommodation for nearly 500 patients, it may be fairly claimed that the young colony of Natal has shown its aged parent "how the thing ought to be done." This will not be doubted when it is stated that the entire transformation was effected in eight days. The *Nubia* belongs to the Peninsular and Oriental Steam Navigation Company and was employed last summer in their China mail service. She is 430 feet long, 49 feet broad, of 5914 tons register, and she has a sea speed of 14 knots. Last October she was chartered as a transport and brought the 1st Battalion Scots Guards to the Cape. She then proceeded to Durban, where she will remain until the present campaign is over. On Dec. 25th a telegram was received by the naval authorities at Durban from the General Officer Commanding the Forces in Natal requesting them to select and fit up a large steamer as a hospital ship with all possible speed. The *Nubia* was inspected, and, being deemed suitable, 130 plumbers, carpenters, and painters were placed on board of her the following day. Most of these workmen were refugees from the Transvaal. By working day and night the ship's whole aspect was changed and her interior completely rearranged, and on Jan. 4th, 1900, she was converted into a floating hospital replete in every detail and ready for the reception of the sick. The *Nubia* had been fitted up for the carrying of 2000 troops, and this entailed an additional amount of labour as all the extensive troop fittings had to be removed ere the work could be begun. It speaks well for the resources of Durban and for the energy of those to whom the work was entrusted that every cot and every fitting had either to be supplied or constructed locally.

Altogether the *Nubia* has accommodation for 474 sick, wounded, or convalescent patients. These are distributed into seven wards named from A to G, beginning in the fore part of the ship with Ward A and finishing in the stern with Ward G. Ward A can accommodate 100 convalescents, B Ward 26 cot cases, C Ward 32 cot cases, D Ward 200 convalescents, E Ward 28 cot cases, F Ward 30 cot cases, and G Ward 30 cot cases, whilst 28 convalescent officers will have the use of the passengers' cabins, in which only the lower berths will be used, the upper ones having been removed to make more room. The convalescent men will sleep in hammocks. The wards are all between decks and can be completely separated from one another by closing the water-tight doors. In Ward F and Ward G, which will be used for the most serious cases, swinging cots are provided, so that when the ship proceeds the motion will be reduced to a minimum, thereby conducing to the comfort of these patients. The floors of the wards have all been varnished and the sides match-boarded and painted white, which adds an air of brightness and cleanliness to their appearance. The vessel is ventilated throughout by means of steam ventilators and electric fans; as a result the wards are always delightfully fresh and cool, even in the middle of the day, when the heat is sometimes oppressive. The operating theatre is situated on the main deck aft, and is provided with all the latest appliances for the pursuit of antiseptic surgery; further aft still is a mortuary, where post-mortem examinations will be conducted. The plentiful supply of fresh water, so necessary at post-mortem examinations, has received due attention. The dispensary opens out of Ward E and a washhouse and laundry are situated on the main deck amidships. The approaches to the wards from the upper decks have been made easier and more adapted to the needs of invalids by having the steps broader and less perpendicular than is usual on board a ship. Two lifts for the use of helpless patients have been fitted. They work by hand and are so contrived as to be free from jerking. The electric light installation has been rearranged and the bright glare subdued by the use of coloured glass shades.

The medical staff consists of six medical men, seven nursing sisters, and 35 attendants. A guard of 10 marines from H M.S. *Terrible*, which is stationed here, are attached. Their duties consist in keeping sentry at the gangway, seeing that due order and discipline are maintained, and that no convalescents leave the ship without permission. During the conversion of the ship Sir William MacCormac paid a visit to it and expressed his satisfaction with the excellence of the work. Whilst inspecting the wards he gave several valuable hints and suggestions. The ladies of Durban came forward with their usual munificence and supplied numbers of deck chairs, small tables, and screens, together with many hanging ferns and palms. These enormously enhance the general comfortable and cheerful appearance of the wards. Every day bundles of newspapers and illustrated periodicals arrive from sympathetic friends and well-wishers.

The patients will be brought down from the base hospitals at Pietermaritzburg and Frere, and will travel in special hospital trains, which are rendered conspicuous by having the Red Cross painted on the carriages. These trains generally consist of seven coaches, of which five are saloons, one a kitchen car, and one a store car. The saloons for the wounded contain 25 berths, which are arranged lengthways with the train. The berths are arranged in two tiers. In the middle of each saloon on either side are a pair of doors similar to those of the luggage compartment of an ordinary train, and the ends of the berths adjoining these doors are so arranged as to facilitate the passage of the patients to the narrow centre passage which runs the entire length of the train. At one end of the train is a store room, fitted with racks and shelves for the rifles and kits of the unfortunate men who are brought on board. At the other end of the train is a kitchen car, provided with a large store, an ice-chest, and every convenience for furnishing the wounded with nourishment, such as beef-tea and jellies, during the railway journey.

The patients will be kept aboard ship until they are able to resume their duties at the front, or if incapacitated from further service they will be sent home as soon as possible. Cloudless blue skies from week's end to week's end, with an occasional shower of rain to vary any possible monotony, the fresh salt smell of the sea, cool breezes from the south-west, and an equable temperature day and night,—these are the climatic conditions of Durban, and it is trusted that they will soon bring back health and strength to these invalids who, having shed their blood in fighting their country's battles, are now justly entitled to every care and comfort that a grateful country can provide.

Durban, Jan. 13th

THE ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS (PART II.).

THE work of this important department of State has increased enormously of late. The present report by Dr. Whitelegge, which was published last week and which is the second and concluding part of the report, Part I. of which was issued in April, affords evidence of this fact. The duties of this department have increased owing largely to considerable fresh legislation having been applied to the ontrol of factories and workshops, and it is no exaggera- on to say that the subject of the health conditions of peratives has received more attention during the past few ears than any other coming under the head of domestic gislation. Generally speaking the report will be found to ontain satisfactory evidence of the care which our laws ake to secure as far as possible the best hygienic con- litions for the circumstances under which a great number f our workmen and workwomen pursue their toil.

DANGEROUS MACHINERY.

Under this heading may be included accidents vhich arise in all industries. Substantial progress has een made with the fencing of dangerous machinery, ut there is an increase in the record of accidents rom certain causes, which Dr. Whitelegge attributes mainly to the following causes. 1. Fuller appreciation and observance of the requirements of the 1895 Act which not only extended the scope of the Act to additional important ndustries but called for the notification of minor accidents formerly not reportable. 2. Increased activity of trade, *especially in the branches which are attended with risk to* life and limb." 3. Increased use of machinery and speeding of machinery. Again, the closer attention which has been given in the department in the last few years to the recording of accidents is doubtless responsible for some part of the increase even among those reportable to the surgeon. The increased number of reports of accidents adds naturally to the work of the department.

DANGEROUS TRADES.

These include the industries of pottery, lucifer match-making, and white lead manufacture. There has been an increase *during the year of the* number of processes which have come to be regarded as dangerous and accordingly fresh demands have been made upon the time of the inspectors. Several inquiries connected in particular with the pottery and lucifer match manufactories were undertaken during the year by Dr. Thorpe and Dr. T. Oliver who were engaged together on the pottery inquiry, while Mr. G. Cunningham joined these gentlemen in the inquiry relating to poisoning by phosphorus fumes in match factories. Both reports were dealt with at length in our columns. Some changes have been made in regard to the special rules applied by the Home Department to factories and workshops. The principal event of the year in connexion with these special rules was the arbitration at Stoke-upon-Trent, which arose out of the amended code for the manufacture and decoration of earthenware and china. The report of the medical officer, Dr. T. M. Legge, gives an account of this and the text of the rules.

LEAD, PHOSPHORUS, AND ARSENIC POISONING.

The report of the medical inspector of factories comprising the industries which are placed under special rules as affecting the health of the operatives is very interesting. He states that the requirements of Section 29 of the 1895 Act are producing very important results and bringing to light illness often contracted from hitherto unsuspected sources. The following up of a notification by a report from the certifying surgeon who sees the patient and visits the works where the illness was contracted has evidently placed a mass of valuable material at the disposal of the Home Office. Thus there is an increase in the total number of reported cases of lead-poisoning, which is due rather to the greater attention on the part of medical practitioners throughout the country to the duty of notification than to increase of plumbism generally. The number of reported cases of lead poisoning in 1897 and 1898 correspond closely. Of the total 457 cases of lead poisoning notified in 1898 as having occurred in china earthenware works 429 were reported in the Midland division which comprises the Potteries district. Dr. Legge makes some interesting observations in regard to the various symptoms referable to lead, to the number of attacks, to the duration of employment of those attacked, and to the degree of severity of the cases Similar observations are made in reference to the white-lead industry. The report of Dr. Thorpe and Dr. Oliver dealing with the question as to how far leadless glazes or fritted glazes are practicable is, of course, here referred to, but the important practical issues which it raises will form the subject of comment in the next annual report. The report also of these gentlemen, in collaboration with Mr. George Cunningham, on phosphorus manufacture and necrosis in match factories is also to be discussed in the next annual report. In view of the announcement by a very large firm of match manufacturers that they have recently succeeded in doing away with yellow phosphorus in the production of a "strike anywhere" match it is probable that further action may be taken in advance of that suggested by the report. Cases of mercurial poisoning are recorded in *connexion with the manufacture of electric filament* lamps. The great source of industrial mercurial poisoning, the silvering of mirrors, has, however, ceased with this process becoming obsolete. The relation of pulmonary diseases to life in a dust-laden atmosphere affords an interesting section, and micro-photographs showing the nature and character of the dust taken from the air of a large silk factory are reproduced in the report. Dust arising also from china scouring and from flax scutching is illustrated in the same way.

COTTON CLOTH FACTORIES.

Certain important regulations came into force in regard to this large industry in 1898 Perhaps the most interesting was that in which a standard of purity for the air was required. This was fixed at a maximum limit of nine volumes of carbonic acid to every 10,000 volumes of air. Mr. W. Williams, the inspector under the Cotton Cloth Factories Acts, was able to obtain evidence of enormous improvement made in the health conditions of weaving sheds in one or two of the factories in which the new requirement had been carried out. Another regulation refers to maintaining an artificial humidity of the air by means of steam. Hitherto it appears that often the steam for this purpose was raised from offensive water. Thus Mr. Williams says that in some of the sources of water used for this purpose it is not uncommon to see the putrefying carcasses of dogs floating and, as he remarks, "operatives can hardly be charged with over-fastidiousness when they object to inhale air impregnated with steam raised from such sources." We notice that a case was reported last week in which certain cotton manufacturers were summoned for using impure water in this way. Mr. Williams trusts that reform will soon be gained in this direction.

WOMEN INSPECTORS.

Not the least interesting feature of this report is the work conducted by Her Majesty's women inspectors. Unhealthy *and dangerous occupations* occupy the premier consideration, but it may be remarked that this comparatively new organisation is *fulfilling its duties admirably.*

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

(Continued from p. 331)

IN the second notice of the final report of Lord Llandaff's Commission which appeared *in THE LANCET, of Feb. 3rd* we gave the result of the deliberations of the Commissioners on the question of the proposed purchase of the undertakings of the metropolitan water companies by the London County Council. It may be remembered that the Commissioners advised that the London County Council should not be allowed to purchase the undertakings, and that they gave the reasons which had led them to come to that decision.

Another very important inquiry which the Commissioners were directed by their terms *of reference* to undertake was whether, in the event of the water companies' businesses not being acquired, additional powers of control should be exercised by local or other authorities, and if so what those powers should be. At the *outset of this inquiry* the Commissioners had to consider the meaning which they should attach to the word "control." *They define control* as "measures by which the due performance of the existing statutory obligations of the companies *can be efficiently* and conveniently secured and enforced." The Commissioners point out that the main obligations of the water companies are contained in the Waterworks Clauses Act (10 Vict., c. 17; 26 and 27 Vict., c. 93) Under the provision of the Metropolis Water Act of 1871 (34 and 35 Vict., c. 113, s. 7) the companies are bound when required by the metropolitan authority to provide and keep a constant supply of pure and wholesome water sufficient for the domestic purposes of the inhabitants who live within their limits of supply. The water must be constantly laid on at a pressure sufficient to make it reach the top storey of the highest houses, but not exceeding certain levels prescribed in the special (private) Acts of the companies. Should the metropolitan authority not insist on a constant supply being given the Local Government Board has the power to do so, but the companies are not required to give a constant supply unless regulations made by themselves and approved by the Local Government Board (to prevent waste, misuse, and contamination of the water, and prescribing also the nature and size of the water appliances inside the dwelling-houses) have been efficiently carried out in at least four-fifths of the premises for which a constant supply is required. The water companies also are free from liability in the case of frost, unusual drought, or other unavoidable cause preventing the supply. Should the cause not be unavoidable the company which fails to give a constant supply is liable to a penalty of £200 and a further penalty of £100 for every month during which the non-supply continues after notice from the Local Government Board has been given to the company, and this penalty may also be recovered by the metropolitan authority in any court having jurisdiction for the recovery of a debt for a like amount. There are also penalties for a failure to give a constant supply under the Water Clauses Act of 1847 to any person who has paid or tendered the water rate. In this case the fine is £10 and £2 for each day of default Under the Act of 1871 provision was made for the appointment of a water examiner who, nominated by the Local Government Board and paid by the companies, was to ascertain whether the water which was taken from the rivers was effectually filtered before delivery to the consumers. The Local Government Board, on the complaint of 20 householders as to the quantity or quality of water supplied, and at their own discretion with regard to the quality of water supplied, have power to appoint a person to inquire and report, and as the result of that report the Board may require a company to remove any ground of complaint. The Act of 1871 contained also certain other provisions to secure the purity of the water supplied by the companies. For example, filtered water reservoirs within five miles of St. Paul's must be covered, and water for domestic use may not be brought into the metropolis in open aqueducts unless it is filtered before distribution.

Another important provision of the Act forbids the companies to resort to any new sources of supply without giving previous notice to the Local Government Board who may prohibit the use of the proposed source. For the public services the companies were obliged to keep a sufficient supply of water for cleansing sewers and for municipal purposes generally, and for this supply the amount of payment must be settled either by agreement or, in case of difference between the company and the local authorities, by two justices. For the water used in extinguishing fires no charge is to be made.[1] Under the Metropolitan Water Act of 1897 (60 and 61 Vict., c. 56, ss. 1 and 2) any water consumer or any local authority (that is to say, the council of any county, borough, or district, the corporation of the city of London, or any vestry, district board, or local board of health in the county of London) has power to bring before the Railway and Canal Commissioners any complaint with regard to the quantity or quality of the water supplied by any metropolitan company or failure to perform any statutory duty. The Railway and Canal Commissioners may impose penalties and direct the removal of the cause of complaint. The local authorities are empowered also to assist the consumers in obtaining the determination of any question of general interest in reference to the quantity or quality of water supplied or with respect to charges made by the companies, and the local authority has power to be made a party to such proceedings and to become liable for the costs.

These enactments, the Royal Commissioners report, cover the whole ground of control as they understand it and provide some remedy for every breach, but criticism may be made of the tribunals and of the principle which runs through all these statutes for postponing action until a breach of some statutory duty has been committed. The Commissioners have been much struck with the ignorance and neglect on the part of local authorities and water consumers of the enactments which were made for their benefit. They quote the example of the Board of Works for Wandsworth which complained of defective supply for road watering, a neglect for which a summary remedy was provided and of which they did not avail themselves. Instead of doing so they contented themselves with writing to the Local Government Board. The Commissioners are of opinion that the apathy of some of the local authorities apparently depends on the complexity of the Waterworks Acts, which, they report, are very much in need of consolidation. The Commissioners considered in some detail the suggestions which were made to them for improving the machinery of control and making it more effective. Mr. Dickinson, a representative of the London County Council, suggested that representatives of that body should be placed on the boards of the companies in a majority. The control thus created would be administrative and would, Mr. Dickinson opined, be more effective than the present system. The suggestion amounted to conferring the whole direction and management of the water businesses upon representatives of the consumers and giving them nearly all the advantages of purchase without any payment of compensation. The representative directors might reduce water charges and thereby reduce dividends to a vanishing point. The proposal was apparently seriously made, but the Commissioners say that it can hardly be regarded as a practical suggestion. Sir John Lubbock suggested that water consumers had a direct interest in the economical management of the profits of those companies which had reached their maximum dividend and he thought it reasonable that one or two representative members might justly be nominated to the boards of the companies to look after the interests of the consumers. The Commissioners report that this proposal exceeds what they believe is meant by control. They consider that things which come more properly under the head of control have reference to the control of the water from the wells and from the Thames and Lee with respect to filtration and to the distribution of the water and its delivery to consumers. The Thames Conservancy Act of 1894 provides that effectual means shall be taken to ascertain from day to day the quantities of water pumped by the companies from the Thames. The engineer of the Thames Conservators has power to enter the premises of the companies and to inspect their appliances. The Conservators have acted with independence and discretion; they are a proper body to control and superintend the quantity of water taken from the Thames, and the only suggestion which the Commissioners make is that provision should be made in case of difference of opinion between the companies and the Thames Conservators as to the payment of any legal costs which may be incurred in an arbitration. In the case of the Lee the statutory provisions are less effective. The Lee Conservators have no control over the gauges which are provided by the New River and the East London Companies. Legislation requires amendment so that the Lee Conservancy Board should have power to inspect all gauges and have the same powers as those possessed at present by the Thames Conservancy.

With regard to the filtration of water the Commissioners point out that although Lord Balfour's Commission recommended that after due inquiry regulations should be drawn up with respect to filter beds no such inquiry has been made, and the Commissioners themselves think that the question is not yet ripe for settlement.

The Commissioners also considered the question as to whether it was advisable to place any restriction upon taking water from the rivers during periods of flood, and they give it as their opinion that the engineers of the water companies are even more disposed to avoid taking flood water than "theory" requires, because when flood water is taken it necessitates more frequent cleansing of the filter beds and is apt to show "slight traces of colour in the filtered water." Several recommendations are made with regard to the efficient control of filtration, and the Commissioners report that it is more useful to test the results of filtration than to impose restrictions on the quality of the water taken. The Commissioners report that regulations are advisable: 1. To ensure that every filter-bed shall have a separate well, so that if a sample taken should prove unsatisfactory it would be possible to immediately see which filter is at fault. 2.

---

[1] In the case of water which has been used for putting out fires no money has ever been paid to water companies. There is a tradition, not, however, very satisfactorily authenticated, that at the time of the great fire of London the flow of water in the New River was interfered with by the incendiaries so that there should be as little chance as possible for the fire to be got under control.

That the rate of filtration in each filter should be automatically recorded and that the apparatus used should indicate he rate of filtration and at the same time record the esult as a diagram. 3. That the Water Examiner should have the right of entry to the works of the companies and a right to inspect every part of the works. 4. That he Water Examiner should possess the power of prohibiting the distribution of water to consumers should he find that any particular filter-bed is defective in operation; he would thus be able to compel the company either to cleanse or improve the filter bed before it was again used. The Commissioners suggest that possibly some power of appeal against the decision of the water examiner ought to be allowed and they see no objection to allow an appeal to an arbitrator under provisions similar to those provided in the Staines Reservoir Act, 1896, ss. 20, 23, but penalties should be imposed on a company which disobeys any order of the water examiner 5. The Commissioners acting on a suggestion made by Sir Edward Frankland suggest that bacteriological laboratories should be built close to the spot from which samples of water are taken in order that the cultivation should take place at once. At these stations experiments should be conducted on the different modes of constructing and of working filters. The Commissioners suggest that the water companies should be required to provide structural and other facilities necessary for testing the samples of water at some place near the works. Sir Edward Frankland suggested three stations, one at Hampton to examine the filtered Thames water, one at Green Lanes at the New River Company's station, one at Lee Bridge at the premises of the East London Company. The Commissioners recommend that examinations of the water which are carried out under the authority of the Local Government Board should in future be more extensive than they have been in the past, and that frequent "bacterioscopic" as well as chemical examinations should be made of the unfiltered river water, of water as it issues from the filter beds, and of the water in the wells and in the mains of the companies, and that the cost of these examinations should be paid by the Local Government Board who should be empowered to recover the expense from the water companies in such proportions as may be arranged. The Water Examiner should have the general control of the examinations and the reports should be sent to him and submitted by him to the Board with his own report. These reports should have the effect of reports under Section 35 of the Metropolis Water Act 1871 and Section 9 of the Metropolis Water Act of 1852. The Commissioners think that the application of the last section should be extended and that the Local Government Board should have power on receiving complaint from any local authority to order an inquiry as to the quality of any water supplied by any company or as to the pressure maintained in the mains. It ought also to be made clear that "frost unusual drought, or unavoidable accident," will not excuse a failure of supply should it be shown that the failure was caused because the works of the company were not in an efficient condition or had not a sufficient capacity for the storage of water.

With regard to the suggestions which had been made by some of the witnesses examined that local authorities should have power of entry to the companies' works the Commissioners report that it would be undesirable to have a dual inspection and that the system would work more smoothly if the control were vested in a Government officer whose reports would be published from time to time so that local authorities would be able to obtain full information. Such authorities might make representations to the officer if they thought his action dilatory The Commissioners, however, point out that the local authorities have used their existing powers of control with very little zeal and efficiency, and they are on that account less disposed to recommend that any additional powers should be given to them.

With regard to the pressure of water in the mains of the companies the Commissioners report that it is reasonable to require that the companies shall record and return to the Water Examiner the pressure which is maintained in the mains at certain specified hours and also shall make a daily return giving the minimum depth of water in the reservoirs. The Commissioners do not advise that any proscription for penalties should be vested in the Water Examiner should the returns show that the companies were not acting up to their statutory duties, but they think that it would be better for him to communicate the returns to any local authority in which such power is already vested to take such action as that authority shall think best.

On the question as to whether an excessive amount of water is pumped from the wells in Hertfordshire the Commissioners decided at an early sitting that they would not reopen the investigation as it had been so recently reported on by Lord Balfour's Commission. They report, however, that the companies were not doing more than the law entitles them to, and that if there is a grievance with regard to the abstraction of water it can be only obviated by an alteration in the English law as to underground water. At the same time they quote the recommendation given by the Balfour Commissioners that "distinct obligations should be laid upon any company or local authority which is allowed to pump water from the chalk for the purposes of public supply, to keep accurate observations of the effect of their operations on the level of the water in the wells from which they pump, and return the results to the Water Examiner under such regulations as may be framed. The great difficulty which we have had to encounter has been in getting accurate and reliable information as to the actual effect of the operations now carried on. The importance of procuring this will increase each year as the limit of what can be taken from any district with safety is gradually being reached." The Commissioners concur in this recommendation, which was made in the year 1893.

On the question of finance the Commissioners report that the Act of 1871 is satisfactory and efficient. There is one blot in the system of audit which should be remedied. Should a difference of opinion arise between the auditor appointed by the Local Government Board and the water companies the matter in difference may be referred to an arbitrator, but in that case the auditor himself has to fee counsel and pay his own costs. The Comissioners think that provision ought to be made for paying the expenses of the auditor out of public money; he is a public officer and he should not be discouraged from asserting his views in opposition to the companies by the prospect of being out of pocket if he does so.

A considerable part of the report is taken up with a review of the evidence given on the waste of water, the control of which, as the Commissioners point out, is rather in aid of than against the companies Lately much has been done in the way of detecting waste by the use of Deacon's water meters. By this means the exact places in which waste is taking place can be localised and the necessary remedies applied Formerly a very large proportion of the waste was due to defective fittings, but some of the companies by careful testing of fittings before they are supplied have succeeded in reducing the amount of waste to a very great extent. Thus the New River Company have induced 95 per cent. of their new customers to adopt fittings which they have examined and stamped as efficient. In some cases the waste of water has, the Commissioners think, been wholly indefensible—as, for example, when taps are left running all night or are even cut off and removed bodily. A great deal of water has been wasted in poor neighbourhoods, in which the agents who manage the properties have put in fittings which satisfy the letter of the regulations but which soon become inefficient, and the magistrates to whom the enforcement of the regulations is committed do not impose penalties in cases in which a tap does not leak when it is put up although its construction is so imperfect that it must necessarily soon prove inefficient. Some of the nothern towns, the Commissioners point out, have adopted a regulation by which it is necessary that fittings must be tested before they are put up In the case of Bradford this change has resulted in a decreased consumption of water. The regulations came into force in the year 1893 when the average amount supplied per head was 24 gallons per day and this amount has now been reduced to a daily average of 17½ gallons. Although the water companies have legal power to cut off the supply of water when a customer wrongfully causes or permits waste this extreme remedy as a matter of fact is rarely resorted to and then only after repeated notices have been sent. Under the Act of 1871 the London County Council have power to require an occupier to provide proper fittings; they have, however, never used that power, and the local sanitary inspectors have no interest in limiting the waste of water. In these circumstances the Commissioners think that the water companies might rightly be empowered to require that all fittings should be approved and tested by themselves and should be renewed and repaired from time to time on their requisition and brought into conformity with properly framed regulations.

With respect to the question of cisterns the Commissioners think that the regulations require intelligent revision and fresh legislation. According to the Metropolis Water Act of 1871 a cistern is a "fitting," but neither the regulations nor the special Acts of the companies prescribe the size or the character of the cisterns which the companies are entitled to require before they lay on water to a house for the purpose of a constant supply. [The Commissioners pending a judicial decision of the question decline to offer an opinion as to the meaning of Sections 24, 30, and 33 of the Metropolis Water Act of 1871. They say that they were not informed of any provisions which compel customers to provide houses with cisterns where a constant supply is not given, although it is obvious that cisterns are essential where the supply is intermittent] Some of the local authorities had caused cisterns to be removed on the ground that they contained much dirt and even dead mice. The Commissioners give it as their opinion that a company should have the power to require that a properly constructed cistern approved by them and of dimensions proportionate to the number of persons likely to inhabit the house should be placed, and should remain in good order and repair, in any house supplied with water, and that the local authorities as guardians of the public health should be empowered to see that the cisterns are properly cleansed and that their construction is modified so as to prevent the fouling of the water, but they should not have the power to order the removal of a cistern unless it is to be at once replaced by another one.

The Commissioners make an important recommendation with respect to information which they think ought to be furnished by the water companies to the Local Government Board. At the present time there is no obligation on the part of the companies to give any information either with regard to their works or their water-supply. All the information at present published by the Water Examiner is supplied as a matter of courtesy, yet these reports have been used in the course of inquiries by Parliamentary Committees and Royal Commissions as authoritative sources of information. The Commissioners report that power should be given to the Local Government Board to prescribe periodical returns containing such information or to call for such plans or documents as might from time to time appear to them necessary or desirable, and it should be a statutory duty of the companies to supply these returns, statements, and plans. The Commissioners further report that in their opinion the power of the Local Government Board to make inquiries might be usefully extended; for example, at the present time the companies are not under control with regard to making any provision for the future wants of their customers. The water undertakings should have reserve capacity of supply in excess of their average wants in order to meet a case of emergency. They ought to exercise prudent forethought in increasing the reservoirs and filter beds and in making provision for the necessary additional pumping power so that the work should all be carried out in time to ensure that the supply may always be constant and efficient. The recommendations which the Commissioners make on the subject of control are in their opinion equally applicable and desirable whether the water companies' undertakings are purchased or not. The Commissioners point out that some witnesses had suggested that in the case of purchase of the undertakings by a public body that body might be left entirely without control because representatives of the people could be thoroughly trusted. The Commissioners, however, without expressing the least distrust of any representative or other authority, think that the measures of control which they suggest should certainly be kept alive in the event of the purchase of the undertakings of the companies by a public authority, although it might be necessary that the machinery to be used for exacting the penalties might have to be altered in the case of dealing with a public authority.

NEWPORT AND MONMOUTHSHIRE INFIRMARY.—The annual meeting of this institution was held on Jan. 31st under the presidency of Lord Tredegar. The financial statement showed that the income amounted to £3296 and the expenditure £2656. It was stated that during the past year Dr. Garrod Thomas and Mrs. Thomas had contributed a fourth donation of £1000 to the new hospital building fund.

THE PHYSIQUE OF THE BOERS.

(FROM A CORRESPONDENT.)

THERE can be no doubt that the Boers have displayed much greater prowess and power as men of war than was ever anticipated. The physical and psychical causes of this capacity for fighting come well within the province of discussion in these columns, for they are scientific rather than political problems. Indeed, the successes of the Boers confirm and enforce all that has been said and attempted to be taught in regard to the preservation of public health. There is not a sanitary reformer who could not deduce many an object-lesson from the history of the present unfortunate campaign. What, after all, is the extremely simple basis on which good sanitation rests? To ensure healthy lives we require plenty of pure air, constant out-door exercise, simple but sufficient food, enough warm clothing, and, in face of the growing prevalence of nervous disease, freedom from gnawing worry and anxiety as to the morrow's bread. The sanitary reformer may also claim to be an advocate of temperance in all things and especially in regard to the consumption of alcohol. This being the ideal, how do the Boers compare with the inhabitants of Great Britain? With but few exceptions the Boers live in the open country. Indeed, it has been said that the ambition of the Boer is to be surrounded by so vast a tract of land that he cannot see the dwelling of his nearest neighbour. Then his occupations are all out-door occupations. He must ride enormous distances to go to church, to do his shopping, to fetch a medical man, or to pay a visit. For his food supply he depends to some extent on hunting, and here we have again a health-giving occupation, to say nothing of the incidental fact that this familiarises him with the use of a gun and enables him to become an excellent marksman. But over and above all these considerations there is the all-important fact that he is exempt from the health-wearing trials alike of wealth and of poverty. Neither surfeited by luxurious living nor starved for want of the necessaries of existence, the Boer leads a life of true temperance free from over-indulgence and from the excess of abstinence. But what in the long run often proves more fatal than, for instance, too much or too little food is that terrible strain on the nervous system due to the want of leisure, the want of freedom from anxiety caused by our overwrought civilisation and the acuteness of the struggle for existence. The Boer mind is not torn and harassed by the ambitious hope of wealth or the constant dread of bankruptcy, of poverty, debt, and starvation. His is an easy-going life. He feels quite safe as to the morrow's existence. His land is not over-populated but under-populated. There is plenty of room for him and his family, however numerous. He has no fear of the bailiff or of the debtors' court. He does not tremble at the thought that he may be discharged from his employment or that the formation of some big trust or syndicate may ruin his business. He has but little experience of the luxuries and the extravagant modes of living prevalent in our western civilisation, but he knows nothing either of our sordid poverty, of our overcrowding, and of all the insalubrious and degrading conditions bred of misery that accompany and put to shame our wealth. It would not be possible to find a "submerged tenth" among the Boers. Therefore the Boers are free from those nerve disorders that so largely contribute to destroy the health of the populations in the great commercial centres.

In so far as they are of Dutch descent, the Boers should be small. The French blood which is mingled with that of the Dutch would not tend very considerably to increase the height of the Boer. The French, though taller than the Dutch, are not so tall as the English. Yet the Boers of to-day are taller, stronger, and possess a more powerful physique than the English. It is quite a common occurrence to meet a Boer six feet six inches in height. Indeed, it has been said that the average height of the Boer is six feet two inches. This is undoubtedly a gross exaggeration, but that such an exaggeration is possible tends to show how striking is the impression made by the tall stature of the Boers. All travellers bear witness to their magnificent physique, especially those who have been among the real Boers, that is to say, those who live in the rural districts well away from the railway lines. The Boer who has taken to town life and acquired town vices may degenerate like other people, but this is not of frequent occurrence, Even those who do live in towns often preserve their primitive and simple methods of existence President Kruger himself is a good example He still keeps up the pastoral habit of going to bed at eight o'clock in the evening and he is up by five o'clock in the morning

But apart from the flesh and bone, the big, strong frames, and the hard muscles developed by the healthy constant out door exercise, the Boers have practical freedom from the diseases due to alcoholism and vice They are not total abstainers but they are remarkably sober and drunkenness is rare among them, Equally important from the health point of view is the fact that the Boer is essentially a moral man Indeed, even were it otherwise, his isolated life in far off farms offers no opportunities for contracting the diseases connected with vice On the other hand, how often are British soldiers punished for drunkenness and invalided through venereal disease Not only is almost every Boer physically fit to take the field and fight for his country, but he is a stronger, healthier, and bigger man than even those who have been selected by medical examination as fit to serve in the British army If the entire male population of our country, without any sort of selection, from the age of 14 to 60 years, were made to stand forth they would present a sorry spectacle as compared with a similar crowd of Boers Let any one, for instance, take his stand in a crowded street in the centre of Glasgow and note how many men will pass him whose backs are straight who have expanded chests and healthy complexions Again in Lancashire, let the observer note the dwarfed figures and pallid faces of the thousands of factory women as they leave the mills And London with its West-end slums festering under the shadow of neighbouring mansions, and its boundless stretch of East end misery, what sort of army would this huge metropolis produce if every male inhabitant were called under arms? In dealing with the sanitary aspect of the question it would be most misleading to compare the British army with the Boers The British army is an infinite minority of the British nation and is composed of men specially selected for their physique With the Boers it is the entire nation that has risen to fight against us, and the fact that primarily interests sanitarians is that there has been no selection among the Boers for all, practically speaking, are physically fit Surely there is something in this marvellous fact to give us pause and to make us think seriously as to whether we are doing all we can to ensure that our people shall possess and preserve those physical qualities without which our empire cannot be maintained If our disasters render us no other service they ought to contribute powerful arguments in favour of still more extensive sanitary reforms Not but that we possess certain sanitary advantages which do not exist among the Boers It may even be said that they have no artificial sanitation whatsoever Their sanitation is of the natural order They have no drains, no sewers, no isolation hospitals, no compulsory notification of infectious diseases, no disinfecting processes, and there is very little medical aid available for medical advisers are few and far between In England we possess all these advantages, and what with workhouse infirmaries, hospitals, and numerous charitable institutions, there is ample provision of medical and surgical aid even for the poorest sections of the population The Boers on the contrary, often suffer for want of such facilities The difficulty of obtaining the assistance of competent surgeons has resulted in the loss of lives that might otherwise have been saved, more especially when Boer women give birth to their first child Nevertheless and as a rule, these women are so strong and healthy that they need but little assistance and it often happens that a day or two after giving birth to a child they are up and busy attending to their domestic duties Again, there have been small epidemics, notably of diphtheria and these were doubtless due to the total absence of any sort of precautions Neighbours will sit in the room of the patient, there is no attempt at isolation or disinfection and of course the disease spreads The women as well as the men have a great amount of outdoor work and exercise, and it is quite certain that very many lives that in England would be saved by medical treatment precautions and care are lost in the Transvaal or Orange Free State Consequently those who survive possess strong constitutions and this also helps to explain why the Boers are such a remarkably fine race

All these facts should induce us to look at home and make us inquire what recruiting grounds still remain where we may find the raw material for the constitution of an effective British army. The most terrible of all the disasters experienced during this war has been the loss of so large a number of Highlanders at Magersfontein The question naturally arises, how are these Highlanders to be replaced? In too many instances their homes exist no longer. The crofter's cottage has been levelled to the ground The hardy race of inhabitants from which our Highland regiments used to be recruited have been driven away Many of them have come to seek employment in the large towns where the process of physical degeneration soon produces its disastrous effects It will be no easy matter to reconstitute the Highland regiments Much the same may be said of the British agricultural population Here also the tendency is to gravitate towards the large towns The decadence of British agriculture to some extent involves the decadence of the fighting qualities of the British race It stands to reason that poverty in a large town is far more destructive of health and physical strength than poverty in a rural district Though the English agricultural labourer is very poor, his wages ranging from 9s to 16s a week, nevertheless, the healthy nature of his occupation makes him the better man physically, and he is more likely to possess the necessary stamina than the worker in the town, even though the latter earns higher wages This is a very grave question and it involves a very deep political problem—namely, whether the great commercial nations do not run a serious risk of being defeated on the battlefield by those nations the bulk of whose population is still employed in agricultural pursuits

Victory in modern warfare will rest with those who possess the best marksmen, or physically speaking, those who have the strongest nerve To keep cool, to take deliberate steady aim, these are the qualities required in action Then between the actual fighting great mobility is necessary and the troops that can best endure the fatigue of long forced marches have the greater chance of being at the right place at the right moment For these purposes the every day occupation of the agriculturist is a far better preparation than the labour of the town worker Let anyone study the distribution of the population in Great Britain and he will at once see the disadvantage of our home condition and the advantage which in this respect the Boers possess The moral is very simple The efforts of legislation and of philanthropy should be directed first to the endeavour to get as large a section of the population as possible back on to the land Secondly, we should strive to make town life as similar to country life as is possible Therefore our streets should be as broad and our houses surrounded with as much open space as circumstances will admit All accumulations of filth which corrupt the atmosphere of towns should be removed with the utmost celerity; and means of communication should be so multiplied and reduced in cost as to enable townsfolk to enjoy the maximum of exercise in the open country If we must fight for our empire such measures are indispensable

To recover from the blows we have received we must calmly consider the whole situation Our national prejudices, our patriotic aspirations, the affection we bear for those who are at the front may be very worthy, natural, and respectable sentiments, but there is no room for them in a scientific investigation We may have very good ethical and sentimental reasons for wishing that lead should be lighter than snow, but they will not alter the verdict given by the scales, and the true patriot to day is the man who dares to look facts in the face and can judge and weigh them impartially

---

ROYAL UNITED HOSPITAL, BATH—The annual meeting of this institution was held on Jan 29th under the presidency of the Mayor The report stated that 1287 in patients had been admitted and that 8941 out patients had been treated, being an increase in each case as compared with 1898 The financial statement showed that the income amounted to £7421 and the expenditure to £7768 The report alluded to the services rendered to the hospital by the late Mr. H Culliford Hopkins first as house surgeon and then, since 1876, as registrar and curator of the museum, and added that his name would be handed down as one of the most zealous of workers for the hospital

Obituary.

SIR THOMAS GRAINGER STEWART, M.D., F.R.C.P. EDIN., LL.D. ABERD., F.R.S.E. EDIN.,

PROFESSOR OF PRACTICE OF PHYSIC AND OF CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH AND PHYSICIAN-IN-ORDINARY TO THE QUEEN IN SCOTLAND.

BY the death of Sir Thomas Grainger Stewart the profession in Scotland has lost one of its most prominent and best known of its members. He died on Saturday morning, Feb. 3rd, the end coming sooner than had been anticipated. For months past he had been laid aside from active work; indeed, since his return from the Congress on Tuberculosis in Berlin he had been more or less of an invalid, confined to the house or his room, and only occasionally able to drive out. Years ago he suffered from more than one attack of acute rheumatism, and it was commonly understood that his heart had not passed through the ordeal quite unscathed; still, he showed little signs of diminished vigour until recurring attacks of influenza seem to have disturbed the balance and initiated a progressive impairment which skill and care could not arrest.

Thomas Grainger Stewart was a native of Edinburgh and was born in September, 1837, so that at the time of his death he was in his sixty-third year. He was educated at the Royal High School of Edinburgh and the University of Edinburgh, and graduated as a doctor of medicine in 1858. After graduation he visited some of the continental schools and on his return acted as house physician under the university professors of clinical medicine in the old Royal Infirmary. At the early age of 25 years he was elected pathologist to the Royal Infirmary and began lecturing on pathology in the extra-mural school at Surgeons' Hall. It was during his tenure of office in this capacity that he did work on the kidney which was incorporated in his book, "A Practical Treatise on Bright's Diseases of the Kidneys," and which has ever since associated his name with kidney affections. He was at the same time a physician to the Hospital for Sick Children. When the chair of Pathology became vacant in 1869 he was a candidate for it, but failing in his application he resigned the post of pathologist to the infirmary, his lectureship and his appointment at the Children's Hospital, and was elected to the post of junior physician in the infirmary. In 1873 he began to lecture on the Practice of Physic in the extramural school, the lecture-room he occupied being opposite the entrance to the infirmary. He at once became the popular lecturer on his subject and his class-room was filled. In the wards of the infirmary also he attracted a large number of students to his cliniques. As a clinical teacher he was clear and systematic and conducted the class by means of question and answer, while the students in rotation listened to abnormal sounds in the patient's chest or otherwise examined him. As a systematic lecturer he was equally clear and precise, so that his doctrine was easily followed even by the junior student. Many circumstances, which need not be detailed, of the Edinburgh Medical School at that time promoted the popularity of a teacher with the gift of clear and easy exposition which characterised Dr. Stewart even in those days. In this respect there is little doubt that he made a marked impression on the teaching of the school, and that the hope that he was wont to express that he would be remembered in the school as having done something to advance the teaching of clinical medicine has been fully realised. After having been extra-mural lecturer for three years the chair of Practice of Physic became vacant by Professor Laycock's death and Dr. Stewart was fortunate in being chosen to succeed him. His success as an extra-mural lecturer was undoubtedly the claim which weighed strongest with the curators of the chair. He thus became the successor of Cullen, Gregory, and Allison. With his appointment to the chair the practice of physic in the University assumed a changed aspect and comparatively few students went for systematic medicine outside the walls of the University class-room. With the increase in the number of students coming to the Edinburgh school which took place soon after that time the class of practice of physic became one of the largest in the University and under the strong hand of Dr. Stewart it never lost its position. From that time consulting practice and honours came to him. He succeeded Sir Robert Christison as Physician-in-Ordinary to the Queen in Scotland; from 1890 to 1892 he was President of the Royal College of Physicians of Edinburgh, and in 1894 he was created a knight. When the British Medical Association was invited to hold its annual meeting in Edinburgh in 1898 Sir Thomas Grainger Stewart was nominated by the local profession to the presidential chair. In this capacity, during the meeting in Edinburgh, he showed to the greatest advantage, all acknowledging that he performed the duties of the post with distinguished success and with a dignity, suavity, and eloquence which had seldom been equalled.

In addition to his book on Bright's disease, to which reference has already been made, he published several monographs and lectures on diseases of the nervous system and on important symptoms—as giddiness and albuminuria. His latest published contributions were some chapters on nervous diseases in the "System of Medicine," edited by Professor Clifford Allbutt. But of all his writings it was his early work upon kidney disease which attracted most attention and which brought him most reputation.

In politics Sir Thomas Grainger Stewart was a Liberal; as a church-man he was a staunch Presbyterian and an office-bearer in St. George's Free Church. He took an active interest in many religious movements and shortly before his death had been re-appointed president of the Edinburgh Medical Missionary Society, having already occupied that position for five years.

In addition to his qualities as a physician, he was a man of wide and general culture, with strong historical and archæological leanings and considerable literary tastes and aspirations. He was endowed with a fine presence and had a gift of ready and graceful speech which made him a valuable ally in controversial times especially when public advocacy of a question was required.

Amongst other honours he was an honorary Fellow of the Royal College of Physicians of Ireland, an M.D., *honoris causâ*, of the University of Dublin and of the Royal University of Ireland; and an LL.D. of Aberdeen University.

The funeral took place on Feb. 7th, from St. George's Free Church to the Dean Cemetery, and the procession was attended by representatives of the University of Edinburgh, by the Fellows of the two Edinburgh Colleges in their official capacity, and by many students, and a large concourse of the general public and his friends and patients.

An old house physician to Sir Thomas Grainger Stewart sends us the following graceful testimony of his indebtedness to his old chief:—"In the Edinburgh Royal Infirmary no post was more sought after or more highly valued than that of resident physician to Sir Thomas Grainger Stewart, and it was indeed deemed a high honour to be selected by him out of the 100 clinical clerks who daily thronged his wards. His house physicians had the privilege of being admitted into the closest intimacy and enjoyed his fullest confidence. They all became his lifelong friends and their future careers were followed by him with the deepest interest. He was an ideal chief—kind, considerate, and ever ready to help and advise. Very rarely did he miss a day in going round the wards he loved so well. None of his house physicians will forget the keenness with which, after the ward visits were over, he discussed with them the various points of interest in connexion with the cases he had just seen, or the valuable lessons they then learnt as the fruit of his ripe and varied experience. Sir Thomas Grainger Stewart was keenly interested in the clinical progress of his clerks and was particularly wel pleased if a case had been well recorded as showing that th student had done his work intelligently and conscientiousl The keynote of his clinical teaching was *method*. Whatev the nature of the case he never permitted any deviati on the part of his students from the exhaustive meth of case-taking which he had himself introduced into University clinical wards, and he frequently inculcated necessity of pursuing the same method of observing all various systems of the body in dealing with private pati and so reducing to a minimum errors of omission in diagr A favourite method of his in ward-teaching was to ta doubtful case admitting of more than one possible diag and then select two or more students to take up and su the rival views and debate the question before the other whose interest was in this way invariably aroused. H failed to impress upon his pupils the importance of ob the general constitution and temperament of a patien

SIR THOMAS GRAINGER STEWART, M.D., F.R.S. EDIN.,
PHYSICIAN-IN-ORDINARY TO THE QUEEN IN SCOTLAND; PROFESSOR OF THE PRACTICE OF MEDICINE AND CLINICAL MEDICINE IN EDINBURGH UNIVERSITY; AND LATE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

proceeding to study the particular ailment His clinical lectures in the Royal Infirmary were always thoroughly practical, and the lecture theatre was invariably crowded His students, and especially his old house physicians who knew him best, had an unbounded admiration for their chief They, more than other men, could appreciate his singularly attractive personality, his high attainments, his magnificent mental grasp and medical acumen He was truly endowed with a large share of what he himself used to characterise as 'the mens medica' We all feel that to day we mourn the loss of a great physician a man worthy of the best traditions of Scottish medicine and whose place it will be hard indeed to fill"

BERNARD EDWARD BRODHURST, F R C S Eng

MR BERNARD EDWARD BRODHURST was born at the Friary, Newark, on Feb 4th, 1822 He obtained the Membership of the Royal College of Surgeons in 1844 and subsequently spent five years at the medical schools of Paris, Vienna, Berlin, Bologna Florence and Rome He reached Rome shortly before the entry of Garibaldi in 1849 and attended the French wounded after Marshal Oudinot's repulse in April of that year For this service he received the Cross of the Legion of Honour and is said to have been offered a baronetcy by Lord Palmerston On returning to London in 1852 Mr Brodhurst was elected a surgeon on the staff of the Royal Orthopædic Hospital In 1859 he passed the examination for the Fellowship of the Royal College of Surgeons of England In 1862 he was elected assistant surgeon to St George's Hospital, but resigned this post after some years on account of his increasing practice preventing him from giving enough time to the affairs of the hospital He was, however, elected surgeon with orthopædic beds

Mr Brodhurst was the author of several works upon orthopædic surgery among which were "Curvatures and Disease of the Spine" "On Anchylosis," and "Lectures on Orthopædic Surgery" He also contributed articles to Holmes's "System of Surgery" and Reynolds's "System of Medicine"

DEATHS OF EMINENT FOREIGN MEDICAL MEN—The deaths of the following eminent foreign medical men are announced —Dr Johannes von Steinau Steinruck of the Bethany Hospital, Berlin, of heart disease in his fiftieth year —Professor Albert Mooren of Dusseldorf, whose name is known not merely as an ophthalmologist but as a historian —Dr William B Canfield Lecturer on Medicine in the Maryland University, Baltimore —Dr Axtell, Lecturer in the University of Denver —Dr William A Hammond, formerly Professor of Nervous Diseases in Bellevue Hospital Medical College New York —Dr Antonio Valenti Lecturer on General Pathology in the University of Rome —Dr Orsi Professor of Clinical Medicine in the University of Pavia —Dr Brunetti, formerly Professor of Pathological Anatomy in the University of Padua —The Marquess Andres del Busto, formerly Professor in the Medical Faculty of the University of Madrid —Dr Constantin Voroshiloff, formerly Professor of Physiology in the University of Kazan

---

ASYLUM REPORTS

London County Asylum Bexley heath, Bexley (Report for the year ending March 31st, 1899) —The asylum was opened in 1898 and male patients were first received on Sept 19th Dr T Stansfield, the medical superintendent states in his report that the patients were "received into what will ultimately be female epileptic and chronic wards, the administrative arrangements for cooking lighting, bathing, and water supply all being of a temporary character." The number of patients to be received was at first limited to 240 but this was subsequently extended to 300 "The laundry was in the hands of the contractors and consequently arrangements were made with the Claybury sub-committee for the washing to be done at that asylum With regard to call-bells, telephones tell tales and fire alarms these essentials are now being arranged for, but in the meantime their absence considerably increases the administrative difficulties and renders the work much more arduous" A fire brigade has been organised and weekly drills have been regularly held Up to the end of December, 1898, there were 265 admissions, and all of these with the exception of eight, were transfers from out-county asylums and from the sister asylums of the county of London 'The character and duration of the disease in the patients transferred were such as to preclude the expectancy of recovery 40 per cent of the patients, put down on their transfers as non workers, have been induced to occupy themselves and thus much valuable work has been done "in the laying-out of airing courts, road making, gardening, and clearing the land." A large day room served as a recreation room and a chapel for Sunday services The wide expanse of heath (Dartford Heath) nearly five miles in circumference immediately adjoining, serves as a beautiful adjunct to the asylum estate and walking parties are sent out over it daily The asylum sub-committee state in their report that a gate porter's lodge has been repaired and is put into use and that plans for the construction of the farm buildings are being carried out Two spray baths have been fitted in the female general bathroom, and it has been decided on the recommendation of the medical superintendent, to have the male general bathroom fitted up entirely with spray baths A well has been satisfactorily sunk and an ample supply of water is obtained and the necessary pumping plant is being fixed up The Kent Waterworks Company supplied water during the progress of the above arrangements The fitting up of the kitchen and cooking apparatus has been completed, while the electric light installation and the fitting up of the laundry are rapidly nearing completion The estate is being completely fenced in, and the land intended for growing crops has been grubbed and steam-cultivated and prepared for planting 'We have from time to time reported,' say the committee "that the sum of £350 000 voted for the building of the asylum would be exceeded We shall shortly be in a position to state with some amount of precision the probable extra cost and will then report accordingly' In addition to the male patients received arrangements have been made for the reception of 480 females and a further 150 male patients, making the total accommodation 930 The sub committee have not considered it desirable to provide a cemetery and, there being no accommodation in the local burial ground, have entered into an agreement with the Plumstead Cemetery authorities for the interment of patients dying in the asylum The Lunacy Commissioners were approached on the subject of the provision of a crematorium at the asylum, but they considered that public opinion was not yet sufficiently ripe or ascertained to warrant the introduction of cremation into public institutions The health of the patients has been good and there were but two deaths during the year—one from organic brain disease and one from general paralysis both being males

London County Asylum, Horton (Report for the year ending March 31st, 1899) —This is the latest asylum for the County of London and consists of two parts—viz, the Horton (Main) Asylum and the Manor Asylum The foundations of the Horton (Main) Asylum—which will practically be a duplicate of the Bexley Heath Asylum—were designed for 2000 patients The time for completion of the superstructure is October 1900 and its estimated cost was £285 000 Since the building has been in progress certain additions and alterations have been sanctioned—viz, re arrangement of the accommodation for the medical and female officers including the provision of a detached nurses' block, at an estimated extra cost of £4500 The fencing of the estate has been carried out at a cost of £3200, and a contract has been entered into for the heating and hot water supply at a cost of £24 560 The Manor Asylum is a temporary building for 700 patients and is nearly completed A portion of it has already been opened and is ready for the reception of patients The water-supply is obtained from a well bored for the purpose but as a precautionary measure the asylum main has been connected with the district water supply so that this will be available should the supply from the boring run short The building is lighted up by gas instead of by electricity as originally intended, and this is supplied by the Epsom Gas Company A cemetery has been provided on the asylum estate and a site of one acre has been apportioned off and suitably prepared for the purpose A working colony for epileptic patients has been decided on and the necessary buildings are now in progress of erection for the accommodation of 300 patients and staff The sub-committee of the asylum reports further details in progress, and it is believed that part at least of the asylum will be shortly ready for the reception of a limited number of patients.

ROYAL ARMY MEDICAL CORPS FUND.

A MEETING of the Central Committee of the recently formed Fund to supply certain necessaries and comforts to the officers and men of the Royal Army Medical Corps now serving in South Africa was held on Feb. 5th at 11, Grafton-street, Piccadilly, by the kind permission of Sir Dyce Duckworth. Surgeon-General Jameson, the Director-General of the Army Medical Service, occupied the chair and was supported by Surgeon-General Muir, the Deputy Director-General. Letters of apology were read from H.R.H. Princess Christian, Lady Rothschild, Lady Wantage, Lady Priestley, and others for their non-attendance. Among those present were Lady White, Lady Knutsford, Lady (Russell) Reynolds, Lady (Douglas) Powell, Lady Brunton, Lady Savory, Mrs. Barlow, Mrs. John Anderson, Mrs. Butlin, Mrs. Pye-Smith, Mrs. Field, Mrs. Walsham, Mrs. Church, Mrs. Charlton, Mrs. Vesey Holt, Mrs. Berkeley Hill, Mrs. Percy Kidd, Mrs. Arbuthnot Lane, Mrs. Liveing, Mrs. A. H. Morgan, Mrs. Charters Symonds, Mrs. Walsh, Mrs. Alfred Willett, Mrs. Johnston, and Mrs. Jameson. Mr. Charters Symonds described how the formation of the Fund came about and read to the meeting the list of vice-presidents. An executive committee was also appointed, and Mr. Charters Symonds announced that so far the amounts received came to a sum of £214.

Surgeon-General Muir proposed that an appeal for funds should be made both in the daily journals and in the medical press. As regards the former at any rate it was decided that only names should be published and not amounts. Small subscriptions were suggested as being most convenient and it was proposed to ask for one of half-a-crown. Surgeon-General Muir also mentioned that the Indian dhoolie bearers would share in the benefits of the Fund as well as the other members of the Army Medical Corps. This is good news, for these men have done admirable work in the most quiet and unassuming way under very trying circumstances. The work of every member of the Army Medical Corps is trying, but possibly that of a stretcher-bearer is the most so of any. A surgeon attending to the wounded under fire is sustained by the necessity for keeping his head cool and his wits about him, but the transport of a wounded man upon a stretcher under a heavy fire, although it may be exciting, is not inspiriting.

In addition to the names already published we have received the following names of members of the committee, including Vice-Presidents and Executive Committee:—Mrs. Church, Mrs. Frederick Taylor, Mrs. Treves, Mrs. Acland, Mrs. Ambrose, Mrs. Anderson, Mrs. Charlton Bastian, Mrs. Brailey, Mrs. Burnett, Miss Burnett, Mrs. Watson Cheyne, Mrs. Origan, Lady Mansfield Clarke, Mrs. Dodd, Lady Fayrer, Mrs. Garrett, Mrs. Hensman, Mrs. Berkeley Hill, Mrs. Frank Howard, Mrs. Liveing, Mrs. Marston, Mrs. A. H. Morgan, Lady Priestley, Mrs. Cooper Perry, Mrs. Steele Perkins, Mrs. Knox Shaw, Lady Savory, Lady Felix Semon, Mrs. Richard Symonds, Mrs. Treves, Mrs. Trueman, Mrs. Cooper Wilkinson, and Mrs. Wornum.

It is suggested that local committees should be formed to work in the provinces in harmony with the central committee. As the object of the Fund is to provide various comforts for the members of the Royal Army Medical Corps now at the seat of war it is obvious that money is required. We shall be most happy to receive subscriptions and to acknowledge their receipt in these columns. If every member of the profession were to contribute at least half-a-crown, while those who are blessed with this world's goods contributed several half-crowns, the Fund would soon mount up to a respectable sum.

Although large subscriptions will naturally be eminently useful yet it is to be hoped that very many small subscriptions, representing an equal number of separate subscribers, will be sent in, for this will show the
mpathy of the profession as a whole.
ions may, if desired, be sent to the offices
ll be forwarded by us to the treasurer
ds, 58, Portland-place, W.).

All postal orders and cheques should be crossed "Holt and Co." and made payable to R.A.M.C. South Africa Fund. Contributions in kind to be sent to Miss Maxwell-Müller, R.R.C., Honorary Secretary, Royal Army Medical South Africa Fund, 100, Victoria-street, S.W.

SICK AND WOUNDED OFFICERS' SURGICAL AND MEDICAL AID FUND.

THE following are among the subscriptions that have been received to this fund. Additional subscriptions are earnestly requested and may be sent to Messrs. Coutts and Co., or to the honorary secretary and treasurer, Mr. Arthur Brodrick, at Hampden House, 61, Green-street, W.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6711 births and 4719 deaths were registered during the week ending Feb. 3rd. The annual rate of mortality in these towns, which had decreased from 30·9 to 22·6 per 1000 in the four preceding weeks, further declined last week to 21·2. In London the rate was 19·6 per 1000, while it averaged 22·3 in the 32 large provincial towns. The lowest death-rates in these towns were 12·6 in Derby, 13·9 in Croydon, 14·3 in Burnley, and 14·4 in West Ham. The 4719 deaths in these towns included 427 which were referred to the principal zymotic diseases, against numbers declining from 578 to 428 in the six preceding weeks; of these 121 resulted from whooping-cough, 110 from diphtheria, 83 from measles, 40 from diarrhœa, 38 from "fever" (principally enteric), 33 from scarlet fever, and two from small-pox. No fatal case of any of these diseases occurred last week either in Derby, Birkenhead, Huddersfield, or Gateshead; in the other
towns they caused the lowest death-rates in C
Brighton, Nottingham, and Sunderland, and the
rates in Wolverhampton, Salford, Preston, and S
The greatest mortality from measles occurred in Pl
Wolverhampton, Preston, and Sheffield; from scar
in Halifax; and from whooping-cough in Wolver
Liverpool, Salford, and Oldham. The mortal
"fever" showed no marked excess in any of
towns. The 110 deaths from diphtheria inclu
London, 21 in Sheffield, five in Leicester, an
West Ham. Two fatal cases of small-pox were
last week in Hull, but not one in any ot
33 large towns. There were 21 cases of smal
treatment in the Metropolitan Asylums H
Saturday last, Feb. 3rd, against 18, 2

at the end of the three preceding weeks, no new cases were admitted during the week, against 10, five, and four in the three preceding weeks The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2179, against numbers decreasing from 3578 to 2287 at the end of the 11 preceding weeks, 174 new cases were admitted during the week, against 180, 207, and 190 in the three preceding weeks Influenza was certified as the primary cause of 109 deaths in London The deaths referred to diseases of the respiratory organs in London, which had decreased from 1221 to 490 in the four preceding weeks, further declined to 432 last week, and were 46 below the corrected average The causes of 72, or 1 5 per cent, of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Plymouth, Cardiff, Salford, Leeds, and in eight other smaller towns, the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Preston, and Huddersfield

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 23 0, 23 3, and 23 4 per 1000 in the two preceding weeks, further rose to 23 7 during the week ending Feb 3rd, and exceeded by 2 5 per 1000 the mean rate during the same period in the 33 large English towns The rates in the eight Scotch towns ranged from 16 6 in Paisley and 20 5 in Leith to 30 7 in Dundee and 40 5 in Perth The 733 deaths in these towns included 25 which were referred to measles, 11 to scarlet fever, nine to diphtheria, eight to whooping cough, eight to diarrhœa, and five to "fever" In all 66 deaths resulted from these principal zymotic diseases, against numbers increasing from 64 to 81 in the four preceding weeks These 66 deaths were equal to an annual rate of 2 1 per 1000, which was 0 2 above the mean rate last week from the same diseases in the 33 large English towns The fatal cases of measles, which had been 32 in each of the two preceding weeks, declined last week to 25, of which 21 occurred in Glasgow and two in Dundee The deaths from scarlet fever, which had been eight in each of the two preceding weeks, increased to 11 last week, and included nine in Glasgow The fatal cases of diphtheria, which had risen from three to seven in the four preceding weeks further increased last week to nine of which three were registered in Glasgow and two in Aberdeen The deaths resulting from whooping cough, which had been eight in each of the two preceding weeks, were again eight last week, and included three in Glasgow, two in Edinburgh, and two in Perth The fatal cases of diarrhœa which had been seven and 23 in the two preceding weeks, declined again last week to eight, of which five were recorded in Glasgow The five deaths referred to different forms of "fever' were all registered in Glasgow, and showed an excess of two over the number in the preceding week The deaths referred to diseases of the respiratory organs in these towns, which had declined from 253 to 172 in the five preceding weeks, rose again to 212 last week, but were 70 below the number in the corresponding period of last year The causes of 49 or nearly 7 per cent, of the deaths in these eight towns last week were not certified

HEALTH OF DUBLIN

The death rate in Dublin, which had decreased from 50 3 to 38 6 per 1000 in the four preceding weeks, further declined to 35 5 during the week ending Feb 3rd During the past four weeks the death rate in the city has averaged 41 9 per 1000 the rate during the same period being 24 4 in London and 23 3 in Edinburgh The 238 deaths registered in Dublin during the week under notice were 21 below the number in the preceding week, and included 12 which were referred to the principal zymotic diseases, against 31, 22 and 10 in the three preceding weeks of these four resulted from measles, three from diphtheria two from "fever,' two from diarrhœa one from scarlet fever, and not one either from small pox or from measles These 12 deaths were equal to an annual rate of 1 8 per 1000 the zymotic death rate during the same period being 1 8 in London and 1 0 in Edinburgh The deaths referred to measles which had declined from 18 to five in the three preceding weeks, further fell last week to four The fatal cases of diphtheria, which had been three, two, and one in the three preceding weeks, rose again to three last week The deaths from "fever,' which had decreased from five to one in the four preceding weeks rose again to two last week The mortality both from scarlet fever and from diarrhœa showed an excess over that recorded in the preceding week The 238 deaths in Dublin last week included 31 of infants under one year of age and 78 of persons aged upwards of 60 years, the deaths both of infants and of elderly persons showed a decline from the number in the preceding week Eight inquest cases and five deaths from violence were registered, and 90, or more than a third, of the deaths occurred in public institutions The causes of 10, or more than 4 per cent, of the deaths in the city last week were not certified

VITAL STATISTICS OF LONDON DURING 1899

Complete statistics relating to sickness and mortality during the year 1899 in each of the 43 sanitary areas of London are summarised in the accompanying table The mortality figures relate to the deaths of persons actually belonging to the various sanitary areas and are the result of a complete system of distribution of deaths occurring in the institutions of London among the various sanitary areas in which the patients had previously resided With regard to the notified cases of infectious diseases in London during 1899 it appears that the proportion of persons reported to be suffering from one or other of the nine diseases shown in the accompanying table was equal to 9 3 per 1000 of the population, estimated at 4,546,752 persons in the middle of the year In the three preceding years the rates were 11 1 10 2 and 8 3 per 1000 respectively Among the various sanitary areas the lowest rates were 5 0 in St Giles 5 1 in St George Hanover square, 5 3 in Strand, 5 4 in St Martin in the Fields, 6 1 in Kensington, and 6 3 in Hampstead, the highest rates were 12 9 in Fulham and in Greenwich, 13 4 in Bermondsey and in Lewisham (excluding Penge), 13 6 in St George Southwark and in Rotherhithe and 15 4 in Plumstead The prevalence of small pox in London showed a further decline during 1899, the new cases notified being only 29, against 979, 225, 104, and 32 in the four preceding years, of these three belonged to Islington, three to Camberwell and two each to Marylebone Hackney Whitechapel, Limehouse and Poplar sanitary areas The number of small pox patients admitted into the Metropolitan Asylums Hospitals during 1899 was 18 and seven remained under treatment at the end of the year The prevalence of scarlet fever in London during 1899 showed a slight increase upon that recorded in the preceding year, the number of cases notified being 18 094, against 25 647, 22 850, and 16 894 in the three preceding years, this disease was proportionally most prevalent in Fulham, St Olave Southwark, Rotherhithe, Greenwich, Lewisham (excluding Penge), and Plumstead sanitary areas During the year under notice 13 641 scarlet fever patients were admitted into the Metropolitan Asylums Hospitals, against 15,982 15 256 and 12 480 in the three preceding years, the number of cases under treatment, which had been 3506 and 2883 respectively at the end of the two preceding years had further declined to 2797 on Dec 30th last Diphtheria showed a slightly increased prevalence during 1899, the cases notified being 13 692 against 13 192 and 11 855 in the two preceding years; this disease showed the highest proportional prevalence in St Saviour Southwark, St George Southwark Newington, Bermondsey Camberwell, and Lewisham sanitary areas The Metropolitan Asylums Hospitals contained 1239 patients at the beginning of 1899, 9569 cases were admitted during the year, and 1679 remained under treatment at the end of December last The prevalence of enteric fever in London during the year under notice considerably exceeded that recorded in any recent year, the number of notified cases being 4456 against 3103 and 3024 in the two preceding years, among the various sanitary areas this disease was proportionally most prevalent in St James Westminster, London City, Bethnal Green, Limehouse Whitechapel and Poplar The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals during 1899 was 1835 against 939 and 1116 in the two preceding years, and 405 cases remained under treatment at the end of December last. Erysipelas showed the highest proportional prevalence in Holborn, St. Luke, Shoreditch Bethnal Green St. George in the East, Newington, and Rotherhithe sanitary areas The 330 notified cases of puerperal fever showed an excess of 83 over the number recorded during 1898 32 belonged to Islington, 27 to Lambeth, 19 to Hackney, 19 to Bethnal

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING THE YEAR 1899.

* Including 339 cases of membranous croup.

† Including deaths from membranous croup.

Green, 19 to Camberwell, 14 to Poplar, 14 to Battersea, and 14 to Greenwich sanitary areas.

During the year under notice the deaths of 87,530 persons belonging to London were registered, equal to an annual rate of 19·3 per 1000, against 18 2, 17·7, and 18·3 in the three preceding years, 1896–7–8; the average rate in the 10 years 1889–1898 being 19 2 per 1000. In the various sanitary areas the lowest death-rates were 11·6 in Hampstead, 12 7 in Stoke Newington, 14·2 in St. George Hanover-square, 14 3 in Plumstead, 15·1 in Lee, and 15 3 in Wandsworth; the highest rates were 24 9 in Holborn and in St. Olave Southwark, 25·1 in St. Saviour Southwark, 25·6 in Limehouse, 27·1 in St. George-in-the-East, 27·7 in St. George Southwark, and 28 4 in St. Luke. Taking the five groups of sanitary areas the rate of mortality during 1899 was 17·8 per 1000 in the north, 18·0 in the west, 18 8 in the south, 22 9 in the east, and 23·0 in central districts. To the principal zymotic diseases 11,147 deaths were referred during the year under notice; 4181 resulted from diarrhœa, 2141 from measles, 1946 from diphtheria, 1717 from whooping-cough, 761 from different forms of "fever" (including two from typhus, 758 from enteric, and one from simple continued fever), 398 from scarlet fever, and three from small-pox. These 11,147 deaths were equal to an annual rate of 2·46 per 1000, against 3·11, 2 57, and 2 77 in the three preceding years 1896–7–8. Among the various sanitary areas the zymotic death-rates ranged from 1·07 in St. Martin-in-the-Fields, 1·09 in St. George Hanover-square, 1·12 in St. James Westminster, 1·16 in Hampstead, 1·33 in Stoke Newington, and 1·35 in Plumstead, to 3 46 in Bermondsey, 3 51 in St. Saviour Southwark, 3 64 in Shoreditch, 3 67 in Newington, 3 78 in Limehouse, and 4 53 in St. George Southwark. The three fatal cases of small-pox registered in London during 1899 were 40 below the corrected average number in the 10 preceding years; one case belonged to Marylebone, one to Whitechapel, and one to Lewisham sanitary areas. The 2141 deaths referred to measles were 700 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in St. George-in-the-East, Limehouse, St. Saviour Southwark, St. George Southwark, St. Olave Southwark, and Bermondsey. The 398 fatal cases of scarlet fever were 557 below the corrected average number; this disease was proportionately most fatal in Fulham, Clerkenwell, St. Luke, St. Olave Southwark, and Rotherhithe sanitary areas. The 1946 deaths referred to diphtheria were 279 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in St. George Southwark, Newington, St. Olave Southwark, Bermondsey, Rotherhithe, and Lewisham (excluding Penge). The 1717 fatal cases of whooping-cough were 718 below the corrected average number; this disease was proportionately most fatal in Chelsea, St. Pancras, Limehouse, Poplar, St. George Southwark, and Newington sanitary areas. The 761 deaths referred to different forms of "fever" were 164 above the corrected average number; among the various sanitary areas the highest "fever" death-rates were recorded in Holborn, Clerkenwell, City of London, Bethnal Green, Limehouse, and Rotherhithe. The 4181 fatal cases of diarrhœa were as many as 930 above the corrected average number; this disease showed the highest proportional fatality in Fulham, St. Luke, Shoreditch, Poplar, St. Saviour Southwark, and St. George Southwark sanitary areas. In conclusion, it may be stated that the mortality in London during 1899 from these zymotic diseases was, in the aggregate, more than 9 per cent. below the average.

Infant mortality in London last year, measured by the proportion of deaths under one year of age to registered births, was equal to 166 per 1000, against 160, 158, and 166 in the three preceding years The rates of infant mortality in the various sanitary areas ranged from 103 in Stoke Newington, 112 in St. Giles, 124 in St. Marylebone and in Plumstead, and 129 in St George Hanover-square and in Hampstead, to 203 in St. Martin-in-the-Fields and in St. Saviour Southwark, 204 in Shoreditch, 205 in St. George Southwark, 207 in Westminster, 216 in Limehouse, and 226 in Holborn.

BOTKIN'S *Bolnichnaya Gazeta* is publishing a series of "Letters from India" from Dr. Kashkadamoff. At present the statistics of the plague epidemic and the hygienic methods adopted for combating it are the subjects principally dealt with.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: F. A. Jeans to the *Ramillies* and J. D. Henwood to the *Benbow*. Staff Surgeons: H. B. Beatty and J. H. Thomas to the *Diana*; R. F. Bowie to the *Europa*; and J. H. Stenhouse to the *Edgar*. Surgeons: Henry N. Stephens to the *Egeria*; Samuel H. Woods and Percy T. Sutcliffe to the *Duke of Wellington*, lent to the *Excellent*; A. E. Kelsey and W. W. Keir to the *Royal Arthur*; P. M. May to the *Mildura*; F. Bradshaw to the *Wallaroo*; J. A. Forrest to the *Howe*; W. B. Macleod to Haslar Hospital; R S. Bernard to the *Torch*; W. L Martin to Haslar Hospital; J. W. W. Stanton to the *Algerine*; L. G. E. O'Leary to Haslar Hospital; F. J. McKenna to the *Lion*; K. H. Jones to the *Waterwitch*; and A. H. Jeremy to the *Phœnix*.

THE IMPERIAL YEOMANRY.

To be Medical Officers, with the temporary rank of Captain: A. C. Fry,; E. T. Vint, Surgeon-Lieutenant-Colonel W. J. Naismith (Ayrshire Yeomanry), H. Manders (Captain and Honorary Major, 1st Volunteer Battalion Princess Charlotte of Wales's Royal Berkshire Regiment), H. A. Lownds (Captain, 2nd Volunteer Battalion the York and Lancaster Regiment), Robert Craig Dun, Douglas Percival, Charnley Smith, and R Mervyn Wilson. J. A. Lea to be Medical Officer, Base Depôt, with the temporary rank of Captain.

ROYAL ARMY MEDICAL CORPS.

Lieutenant E. McDonnell and Major C. Birt have arrived at Portsmouth for duty with No. 7 General Hospital. Lieutenant Colonel W. W. Kenny, Captain G. A. T. Bray, and Lieutenant G. J. S Archer have left Woolwich. Lieutenant-Colonel J. G. MacNeece has arrived at Portsmouth for charge of No. 7 General Hospital, being mobilised for South Africa. Major J. Moir, medical officer in charge of troops, Esquimalt, British Columbia, is ordered home. Captain H. A. Berryman has arrived at Colchester.

The undermentioned Lieutenants to be Captains:—George E. F. Stammers, Charles F. Wanhill, Wilfrid E. Hudleston, Martin P. Corkery, Frederick J. Gaine, Leonard Addams Williams, Malcolm Mac G. Rattray, John H. Power, Richard E. G. Phillips, Thomas H. M. Clarke, D.S O., and Edwin W. P. V. Marriott.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant A. Macdonald to be Surgeon-Captain, and Surgeon Captain Simon Linton, 1st Fifeshire Volunteer Artillery, to be Surgeon-Captain.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Lieutenant-Colonel C. B. Stoney, 3rd Battalion the Prince of Wales's Leinster Regiment (Royal Canadians), resigns his commission, with permission to retain his rank and to wear the prescribed uniform on his retirement.

VOLUNTEER CORPS.

Artillery: 1st Cumberland: Surgeon-Lieutenant George Martin resigns his commission and is appointed Captain. 2nd Glamorganshire: Surgeon-Lieutenant C. H. D. Morland resigns his commission *Royal Engineers:* 1st Lancashire: Henry Halton to be Surgeon-Lieutenant. *Rifle:* 3rd Volunteer Battalion the Cheshire Regiment: Second Lieutenant Bernard Hale Woodyatt resigns his commission and is appointed Surgeon-Lieutenant. 2nd Volunteer Battalion the Welsh Regiment: Surgeon-Lieutenant A. W. Sheperd to be Surgeon-Captain. 3rd Volunteer Battalion the Essex Regiment: Daniel Mowat to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Duke of Cambridge's Own (Middlesex Regiment): Thomas Christopher Cummins to be Surgeon-Lieutenant.

TRANSVAAL WAR NOTES.

In the House of Commons on Tuesday, Feb. 6th, in reply to Sir W. Foster, Mr. Wyndham said that 368 officers of the Royal Army Medical Corps are employed in South Africa, 377 at other foreign stations, and 111 at home. 133 civil surgeons are employed in South Africa and 28 more are under orders to go. 112 retired pay officers are employed at home.

At a meeting of the Imperial Yeomanry Hospital Committee held at 20, Curzon-street, W., on Feb. 5th, Lady Georgiana Curzon stated with reference to the position of affairs in regard to the hospital and its equipment that three-quarters of the equipment would be shipped by Feb. 7th, and two-thirds was already at sea. The medical men would leave in the *Majestic* on Feb. 10th with the exception of Lieutenant-Colonel Sloggett, R.A.M.C., military commandant of the hospital and principal medical officer, and Mr. A. Fripp, chief civilian medical officer, who would go in the *Norman* on the same date, accompanied by 114 members of their staff. The Prince of Wales will inspect the hospital staff at Devonshire House to-day (Friday). Mr. Charles Stonham, F.R.C.S. Eng., senior surgeon, Westminster Hospital, Surgeon-Captain, Middlesex Yeomanry Cavalry, has been appointed senior surgeon.

Dr. Mario Nascimento, a Portuguese doctor, lately Mayor of Lourenzo Marques, has volunteered his services in the British ambulance at Natal and has been accepted.

Princess Christian and Princess Victoria of Schleswig-Holstein visited the sufferers from the war at Netley Hospital on Feb. 6th. Their Royal Highnesses were received at Netley Pier by Colonel Creagh and Colonel Charlton, R.A.M.C. On arrival at the hospital their Royal Highnesses were conducted through the wards, in which were some 300 patients.

Nurse "Lawrence," mentioned in the second paragraph under the above heading last week, should have been Miss Eda C. Laurence, sister of Judge-President P. M. Laurence, of the High Court of Griqualand West, Kimberley, and daughter of the Rev. P. Laurence of Walesby, Lincs.

FIELD HOSPITALS AND AMBULANCE FOR HILL WARFARE.

Lieutenant-Colonel C. J. McCartie, I.M.S., has issued through Messrs. W. Thacker and Co., Creed-lane, E.C., a pamphlet recommending several changes in our field hospital system to make it suitable for mountain warfare. The main points of his plan are to divide the hospital equipment into (*a*) indispensable and (*b*) reserve, and to have the "indispensable" carried by porters accompanying the troops. Each regiment now takes two field panniers on a mule, but Lieutenant-Colonel McCartie believes that instead of this a regiment might take all the indispensable articles of the panniers in two knapsacks of about 35 lb. each on two porters. For a brigade of four regiments and a battery there would be 10 porters attached to corps and 32 porters to carry all the articles that are really necessary for the two field hospitals belonging to the brigade, whereas at present the equipment is carried by about 105 mules with 35 drivers. Porters can keep up with the troops over hills or snow, but mules cannot do this. There are 13 medical officers in the brigade Each would be accompanied by a porter carrying an amputation case, chloroform, and everything necessary for ordinary operations. With the present system an operation cannot be performed on the march without unloading and re-loading a mule, and if the mules are left behind no instruments or lanterns are obtainable. The other 29 porters would carry medicine, milk, soup, dressings, &c., and about 14 lanterns. The ambulance of a brigade now provides for the carriage of 49 patients in dandies and 160 on riding mules, besides the four stretchers for each regiment. There are 306 bearers for the dandies Lieutenant-Colonel McCartie describes and figures patterns of dandies and stretchers which he considers to be much superior to the regulation ones

THE FAMINE IN INDIA.

India has been sorely tried of late years It will be seen from our Special Correspondent's letter published in the present number of THE LANCET that plague continues its ravages and from the official statement furnished by the Secretary of State for India to the Lord Mayor that the country is suffering from a terrible famine—terrible alike in the great extent of its area of prevalence and the number of the population affected.

JOURNALISM AND THE WAR.

We refer our readers to the latter part of an article, "Musings without Method," in *Blackwood's Magazine* for February for a trenchant criticism on journalism in connexion with the war in South Africa It strikes us as well worthy of being read at the present time.

The annual distribution of prizes to the London Companies the Volunteer Medical Staff Corps will take place on Feb. 17th, at 8 P.M., at the headquarters of the corps 51, Calthorpe-street, Gray's Inn-road. The prizes will be distributed by Surgeon-General H. S Muir, Deputy Director-General, Army Medical Service.

Correspondence.

"Audi alteram partem."

NEALE'S DIGEST: A RECOGNITION OF THE AUTHOR'S LABOURS.

To the Editors of THE LANCET.

SIRS,—No doubt most of your readers are aware that Dr. Neale has recently published the supplement to his Medical Digest, which completes and brings down to date that admirable guide to the British medical literature of the last 50 years; but it is not likely they have any idea of the enormous and unremitting labour this self-imposed task has cost the compiler. The work of making his index and preparing it for the press has involved an average of four hours per day for more than 50 years. This labour has not only been without remuneration, for the publication of the Digest has never been profitable, but it has been carried on year after year at great cost to Dr. Neale, who with rare determination has cheerfully persevered in a task which he originally undertook for the benefit of science and of his profession rather than for his own pecuniary advantage.

It seems to the undersigned that it would be unbecoming to the profession he has worked for if Dr. Neale's labours were allowed to pass unrecognised, and they have, therefore, decided to invite the members of the profession throughout the British Empire to contribute to a fund which will enable them to present Dr. Neale with a suitable testimonial, as a recognition by his professional brethren of his long-continued and invaluable labours on their behalf. Obviously, it would be premature to discuss the form of the testimonial until the amount of the contributions can be ascertained, but all the subscribers will be communicated with before a decision is arrived at.

We are, Sirs, yours faithfully,
W. S. CHURCH,
President of the Royal College of Physicians.
WM. TURNER,
President of the General Medical Council
H. G. HOWSE,
Senior Vice-President of the Royal College of Surgeons.
THOMAS BRYANT,
President of the Royal Medical and Chirurgical Society.
R. DOUGLAS POWELL,
President of the Clinical Society of London
W. WATSON CHEYNE,
President of the Pathological Society of London.
FREDERICK T. ROBERTS,
President of the Medical Society of London.
ALBAN DORAN,
President of the Obstetrical Society of London
W. H. BROADBENT,
President of the Medical Graduates' College and Polyclinic.
HENRY POWER,
President of the New Sydenham Society.
JONATHAN HUTCHINSON,
Honorary Secretary of the *New Sydenham Society*.

P S.—Subscriptions may be sent to Mr. J. Y W. MacAlister (Librarian of the Royal Medical and Chirurgical Society), 20, Hanover-square, London, W. It will save him much trouble if cheques are made payable to "Bearer" and crossed "National Provincial Bank—Neale Testimonial Account."

"THE CONFERENCE AT NEWCASTLE AND THE MIDWIFERY QUESTION."

To the Editors of THE LANCET.

SIRS,—I have pleasure is answering the questions and suggestions of Mr. Chas E S. Flemming in his letter appearing in THE LANCET of Feb 3rd (p. 338). Radical changes of any kind in systems or schemes which have enjoyed much support for a number of years usually meet with strenuous opposition from some source or other, and I can only express surprise that more has not been shown against my suggested scheme as sketched in THE LANCET of Jan. 20th (p. 197). I feel bound to attribute this to a very wide sympathy which my suggestions have elicited.

Mr. Flemming devotes nearly the whole of his letter to the question of responsibility.' Now, for the life of me I cannot see why he should be so anxious over this point, especially as I myself can observe other points in my scheme which would seem to call for more insistent questioning—as they might be viewed from the standpoint of critics. I refer your correspondent to the division of responsibility as it obtains between a medical practitioner and either his qualified assistant or his trained medical or surgical nurse. Moreover, it should be in the power of an appointed district obstetric practitioner to dismiss any registered obstetric nurse for malpraxis or certain irregularities at a moment's notice, and such dismissal should be followed by inquiry and loss of certificate if the offence were considered sufficiently serious. But whoever hears of serious malpraxis on the part of either an assistant or a qualified medical or surgical nurse? The circumstances under which chief and subordinate work practically forbid it; and so it would be with the properly qualified registered obstetric nurse. I would draw your correspondent's attention to the fact that I gave no fees as appropriate to a Bill. I never mentioned the word Bill in my scheme or in paragraphs referring to that scheme. The whole question of right adjustment of all fees is one for after-consideration, the main question being, Does it seem feasible that midwives should be replaced by the coöperative working of medical man *plus* obstetric nurse?

To the question, "What is the intended effect of the medical man's visit as suggested in the latter paragraph of Clause 4?" I answer that the visit would be one made in order to confirm or not the obstetric nurse's opinion and the patient's belief that she is in a satisfactory condition—a simple confirmative and disciplinary visit, to satisfy everybody and to remind the nurse that her finished work is subject to the inspection of a medical man. Mr. Flemming is labouring under an apprehension regarding Clause 7. He forgets that the working-classes would not be obliged to retain the joint services of an appointed medical man and obstetric nurse, for they would be at liberty to engage an ordinary practitioner if they chose. Under my suggested scheme I do not expect quite every woman to rush to the combination although I do believe that more would take advantage of it than of a midwife as we now understand her, and thus a badly paid and to many practitioners an undesirable class of work (so they say) would be diminished in amount. Likewise Mr. Flemming's anticipation of "complications between neighbours and the difficulties of enforcing the rule" is one of an alarmist. Consultations would never be held with other local general practitioners, but with outside consultants of standing, as rarely as they would be required, and the appointed obstetric practitioner would go on with the case afterwards. *The appointment of obstetricians would take place annually.* Women of the general public would not be obliged to engage the combination, supposing either a medical man or a nurse were unpopular.

I am, Sirs, yours faithfully,
HAYDN BROWN.
London, Feb. 3rd, 1900.

CONTAMINATED COCKLES.

To the Editors of THE LANCET.

SIRS,—You are no doubt aware that we had in the city of Belfast in 1898 what might have been considered an epidemic of typhoid fever, and if now the number of cases reported has fortunately very materially decreased we still have more cases amongst us, compared with the other parts of the United Kingdom, than would be considered normal. Notwithstanding the most diligent inquiries the local authorities and the local medical profession have failed to trace the origin of the epidemic. I suggested from time to time that the sale of cockles, collected on the shores of estuaries contaminated by sewage, was perhaps one of the sources which would account for the prevalence of typhoid fever in Belfast. Cockles are mostly consumed here by the poorer classes and these classes seem to furnish more than their proportion of typhoid fever cases. We have in Belfast about 700 Jews, mostly of Russian origin and poor, who all strictly adhere to the Mosaic code of diet, discarding amongst other food all animals living in the sea not covered by scales. As President of the Hebrew community here I have made inquiries and no case of typhoid fever has been reported amongst the members of the congregation for many years past.

My object in bringing the matter before you is to draw attention to this fact, and if similar experience is recorded elsewhere you will no doubt use your powerful influence in connexion with the other members of the medical press to obtain some legislation to prohibit the collection of cockles and oysters from any estuary that might be contaminated by sewage.

I am, Sirs, yours truly,
OTTO JAFFE.
Belfast, Feb. 5th, 1900.

THE DURATION OF THE IMMUNITY CONFERRED BY INOCULATION AGAINST TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—In a leading article on Anti-typhoid Inoculation in THE LANCET of Jan. 27th you state that "it is necessary that the effects should last for a considerable period. On this point we have as yet little information." This raises the question whether we have any scientific data or guide to fix approximately the effect of this or any other inoculation.

It appears to me that there is one circumstance which might and does help us in coming to some conclusion. Dr. W. B. Ransom in his address on "Immunity to Disease" says, "In small-pox, scarlet fever, measles, syphilis, the protection is considerable and long; in typhoid fever it is fairly well marked; in diphtheria more transient; while in pneumonia, erysipelas, influenza, and cholera it is hardly at all apparent." Of course he means an attack of disease naturally acquired and which confers immunity. This may be in diseases naturally acquired. I think in inoculation the period of incubation of disease does help us in coming to some conclusion on the subject. In those diseases in which the period of incubation is longer the effect of inoculation is also longer. One hears a good deal about plague and cholera inoculations. I think the effect of inoculations in these cases must be very transient in men. We are told to look at the statistics. As we all know, statistics can prove anything. What we as scientific men want is scientific explanation to guide us. It further appears to me that inoculation that takes a long time in producing its effect—viz., malaise, fever, &c.—confers immunity which ought to last for a long time too. This leads us to another conclusion. Inoculation can confer a longer immunity only in those diseases in which progress of the disease and morbid changes in the organs or glands which they particularly affect are slow and gradual. In those diseases in which progress is very rapid inoculation cannot be of any advantage such as plague, cholera, and influenza.

For these reasons I venture to think that "anti typhoid inoculation" will prove of great service, but there should be two or three inoculations at intervals before a marked and permanent effect is produced. Though it has been demonstrated that immunity is due to a vital action of the cells of the body, alteration, however slight, in structure of glands affected has something to do with it. Of all the diseases in which inoculations have been performed in only two of them is there a marked benefit—vaccination against small pox and inoculation against rabies. The reason is that entire lymph in one case and emulsion of the entire substance of the medulla oblongata in the other are used, and not dead bacilli toxins or proteins separately. It shows that to have any marked effect there should be something more than "anti-infective" or "antitoxin" substances.

Copeman seems to have found the micro-organism of variola. I think, for practical purposes, it will be an evil day for science and humanity if such a bacillus is isolated and we leave off using vaccine lymph as protection against small-pox.

I am, Sirs, yours faithfully,
P. J. DAMANIA, D.P.H.
Portley, Caterham, Feb. 4th, 1900.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—If Mr. Whiteford will do me the honour to reconsider what I have endeavoured to set out in the three cited recent numbers of THE LANCET he will find that the apposition of facts has answered his question by demolishing the proposition on which it is based. But there is no difficulty in giving a categorical reply. Speaking of the open or Skinner's mask method of administration, Mr. Whiteford's question is: "If the patient does not absorb a similar dose of chloroform in each case, why do we get a similar result? I am still waiting a reply to this query."

The answer is that *we do not get a similar result.* As I have stated, there lie upon my table newspaper reports of 83 inquests upon persons killed by anæsthetics during the year 1899 in England alone; and some 80 per cent. of these deaths occurred before operation commenced. This 80 per cent., therefore, died of the administration apart altogether from contingencies in the course of an operation. Reading between the lines these 83 inquests represent probably 200 deaths from anæsthetics. Assuming that for each irretrievable case of poisoning four cases are resuscitated by artificial respiration, we have yearly 1000 cases in England in which operative proceedings are broken in upon and a most distressing anxiety is suddenly thrust upon all the medical men who are present. In a country town such a death may also half ruin the career of a young practitioner and prejudice his professional usefulness for years afterwards. These deaths are a matter of intense professional and public concern, and they are due to a want of exactly that uniformity of results which Mr. Whiteford assumes to occur. Again, Mr. Whiteford's argument if sound would merely shift on to the administrator personally, and on to all the medical men who have stood by without protest, that blame which rests upon our present *rule-of-thumb method of administration.* Mr. Whiteford's argument would also divert us from the real remedy, which, as I submit, lies in the direction of measured dosage.

Mr. Whiteford has left unanswered two questions which I asked him, and I take this opportunity of thanking him in advance for replies in his next letter. Those questions were: 1. Can he show us any method of measured dosage other than the volumetric administration of air charged with the vapour of the anæsthetic? 2. Can he show us any apparatus by which precise and registrable dosage can be secured other than the improved Krohne inhaler?

The administration of "chloroform from an air-tight inhaler" combines asphyxia with chloroform poisoning. I agree with Mr. Whiteford in condemning it utterly. Asphyxia *plus* chloroform poisoning was, in fact, the vice of the old Junker apparatus. Yet even to day many writers seem not to know the difference between the old Junker apparatus and the modern Krohne inhaler. The Krohne inhaler has, of course, a respiration orifice many times larger than the area of the glottis and which is always open, so that no element of asphyxia can be imported into the use of the apparatus. It also has the feather-indicator, the action of which displays the currents of the respiration with all their variations to every one in the room. This relieves the administrator of watching the movements of the chest. It also prevents his depending upon chest-movements which, with closure of the glottis, are abortive and misleading—though apparently active. In diphtheria and other conditions involving obstruction of the glottis the movements of the chest, as is well known, become specially strenuous, but they are a measure of the difficulty of respiration—not of its efficiency. These persistent chest-movements, nevertheless, are often a trap to the administrator.

As several thousands of the improved Krohne inhalers are now in use all over the world deaths now and then occur with them. I have myself seen administrators use the Krohne inhaler so as to "*blow chloroform* at the patient." Of course I advocate the Krohne inhaler *used as I have described.* The injection of chloroform air into the vulcanite face-piece must be made *at the ebb tide of each expiration* so that the *on-coming* inspiration may sweep the dose of chloroform air well into the lungs. In that case we do not "blow chloroform at our patient"—we blow it into the recesses of his lungs, and all we have to do is to realise that chloroform is a very powerful poison and that we must think in fractions of a minim for each inspiration and not as if we were slopping chloroform about by the ounce. Administrators there are who complain that they "cannot get their patients under with the Krohne inhaler." If such administrators be observed it will be seen that they have no sense of time as to the proper phase-moment of the respiration cycle at which the chloroform air is injected into the face-piece. Some such men lose or gain time and work all round the respiration cycle like a man who gains or loses a whole bar in a waltz every time he gets round the room. The result is that sometimes they cannot get their patients under, sometimes they get them under too well. If the chloroform air be injected into the face-piece during expiration it is "blown at the patient," but it is at once reflected into the faces of the medical men and nurses by being blown out of the mixing box. If the administrator have a sense of time but no other sense he will stick to the beat of the expiratory phase of the respiration cycle, pump very strenuously, and use bad language to the inhaler. Sometimes he will stop up the respiration orifice and by hook or by crook will stupefy his patient, the stupefaction being a combination of asphyxia and anæsthesia If he lack a sense of time as well as other sense, when not being able to get his patient under has driven him to desperate pumping, he may suddenly lose half a beat and drop into the inspiration phase of the respiration cycle. He then provokes spasma glottidis and the sequence of phenomena which I have previously described.

It is quite true that "the depth and frequency of the respiration vary in different patients and in the same patient at different times." But Mr. Whiteford's conclusion upon this is a *non sequitur.* In using the Krohne inhaler we have the patient recumbent; the inhaler is then fitted carefully and comfortably to the face, a little pleasant small talk *follows until the patient has realised that he can breathe* as comfortably and freely with the inhaler on as with it off. Under this manœuvre the patient's respiration generally becomes calm and regular. But *in any and every case* the squeeze of the bellows-ball *must* be *timed to* the ebb-tide of the expiration so that the on-coming inspiration sweeps the chloroform air, diluted with the inspiration current, into the recesses of the lungs. So much for timing to the beat of the phase-moment of the respiration cycle. As to amplitude of squeeze—which governs not the time of the injection but the amount of each dose—that can be controlled perfectly with a very little previous practice, and be made to deliver from one to 100 cubic centimetres of air saturated with chloroform vapour. In maintaining anæsthesia a squeeze of small amplitude for every third or fourth inspiration generally suffices. Here one must be guided, as Mr. Whiteford says, rather "by the state of the pulse, respiration, and pupils than by any hard-and-fast line as to the amount of chloroform" used. Assuming that the injections of chloroform air are properly timed for the successive inspirations and that the amplitudes of squeeze are properly regulated, our position is improved immensely over the open method, in which we never really know how much has been propelled into the lungs. But we still have indeterminate factors to cope with, and the effect, or real dosage, depends on the balance between ingestion and egestion—as with other drugs whether ingested by the stomach, by hypodermic injection, or by inhalation through the lungs. In hot weather, for instance, exhalation by the lungs and skin are much more active than in cold weather, and there are other factors which will alter the balance of real dosage. The final adjustment of the dosage is a matter of touch—like pitch in playing the fiddle. But to have an implement which responds perfectly to all the intelligence that an administrator can hope to possess is a vast help and security. That is what the Krohne inhaler is to the man who has initiated himself into its use. Practically its face-piece is a domed cell, standing over the mouth and nose, made air-tight to the face below by means of the rubber inflator, but absolutely open at the top and there furnished with the feather indicator which displays the currents of the respiration. Through this one can breathe all day as well as if it were not *on*, and there is no element of asphyxia unless some sage stops up the respiration orifice and converts it into an old Junker apparatus. The rest of the apparatus is a mere addendum by which any volume of air can be pumped through chloroform in a graduated bottle and be propelled into the face piece. The chloroform air, being heavier and a shade colder than the atmosphere, falls on to the mouth and nose at the moment of the pause after the expiration is finished. By the next on-coming inspiration this chloroform air, more or less mixed with the inspiration current, is swept into the recesses of the lungs. The outcome is that, with a little practice, a sufficiently precise and measured dosage — summed up and registered by the graduated bottle—can be secured. This serves as a "dead reckoning," but it does not supersede the astronomical observations with which a prudent captain checks off his dead reckoning as often as opportunities occur.

Again, there is always the time-factor. If an administrator work his bellows with such amplitudes as to inject, say, 10 minims of chloroform into the 12 or 13 cubic inches of blood that lie between the terminals of the pulmonary and coronary arteries—*not giving the time necessary for the distribution of these 10 minims of chloroform into the large mass of blood in the general circulation*; in that case the use of a Khrone inhaler will not keep the patient alive Here the time-factor is the determinant. We kill our patient with an insignificant amount of chloroform, just as with a hammer of insignificant weight we *fracture* the skull of a porter who carries a hundredweight on his head comfortably by means of the distributing ring which is known as the porter's knot. In these cases of sudden death before operation it is the stroke of the concentred action — the local poisoning of the pulmo-cardiac blood—which kills.

The object to be aimed at in inducing an anæsthesia is so admirably described by Mr. Whiteford that I ask permission to reproduce it prominently. It runs thus:—

"I set out with the object of inducing anæsthesia slowly and quietly in from about 10 to 12 minutes and of maintaining this state with regular pulse and respiration and with contracted pupils."

I could not wish for a more lucid or more concise set of sailing directions. They are just what I had the advantage of being taught as an apprentice *now some* 50 years ago, and they have served me well ever since. For *some 40 years I was in the habit of giving chloroform off* a towel, or anything else, simply by the light of those principles and with the rule to *go gently at first*—so as to provoke no cough, no resistance, no spasm of the glottis. I have had large experience of chloroform, and should never think of using anything else. I have never had any sort of anxiety about my chloroform in any single case. But I confess, now I have got used to the improved Krohne inhaler and realise the true significance of these deaths, that I should think it a crime to go back to a towel or a Skinner's mask.

I am, Sirs, yours faithfully,
Manchester-square, W. JAMES EDMUNDS.

THE ANTI-VACCINATION PROPAGANDA.

To the Editors of THE LANCET.

SIRS,—I observe from reports in the provincial press that a member of the Anti-Vaccination League has resumed the delivery of the lectures which he gave last year and which were illustrated by lantern slides of (what is called in the advertisement of the lecture) "a *painful* character" to general audiences. I shall be glad if any of your readers who may be aware of the proposal to give such lectures in their own immediate neighbourhood will kindly communicate with me as soon as possible, in order that efforts may be made to place the lecturer and his misrepresentations in their proper light before the public.

I am, Sirs, yours faithfully,
FRANCIS T. BOND, M.D. Lond.,
Gloucester, Feb 6th. *Honorary Secretary, Jenner Society.*

THE HOSPITALS AND THE SICK AND WOUNDED IN THE SOUTH AFRICAN WAR.

To the Editors of THE LANCET.

SIRS,—I have just been to the Army Medical Department and have learnt from Surgeon-General Jameson *himself* that this question to the hospitals, "What beds have you available?" has been misunderstood The department did not wish to oust civilians to make room for soldiers, but merely to inquire *at which hospitals there were wards now empty* which for want of money or other reasons could not be opened and which would therefore be available for soldiers if the Government were to pay the cost of opening them. To this question we at the London Hospital are obliged to answer that we have no beds "available" but with sufficient notice we shall, as will every other hospital, be only too glad to do our best to help. As a fact I do not think any civil hospital will be asked, and I found this opinion on the fact that the Army Medical Department, or rather the Soldiers and Sailors Help Society to whom is relegated this work, are refusing offers of completely equipped hospitals from people in all parts of the country. There are a very large number of beds vacant in the military hospitals and huts are being erected to accommodate any overflow. Tempted as every hospital chairman must be to say, "The whole of my *hospital is open to the wounded soldiers*" because of the advertisement thereby attained, we all have duties to the sick and injured civilians, especially in East-end hospitals where we have no hospital within a cricket-ball's throw to take the cases which we may have to refuse.

I am, Sirs, yours faithfully,
SYDNEY HOLLAND,
Bryanston-square, W. *Chairman, London Hospital.*

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

To the Editors of THE LANCET.

SIRS,—Whatever may be said of the value of Royal Commissions as a rule there can be no doubt that the members of the latest Royal Commission on the Metropolitan Water-supply have rendered to all interested in the question this service: they have summarised the position. It is true that the inquiry has been unusually protracted and it is also true that a considerable time has elapsed between the termination of the sittings and the publication of the present report. On this latter fact, however, little surprise can be expressed when the very comprehensive nature of the report is realised *by a careful perusal and consideration of its contents.* The previous history of inquiries on the subject had to be reviewed, the rapid developments in regard to modern requirements had to be taken carefully into account, and fresh possibilities under a series of abnormally dry seasons had to be faced before Lord Llandaff's Commission could get to work on the special subjects upon which Her Majesty through her Ministers on May 1st, 1897, "deemed it expedient that a Commission should forthwith issue to inquire."

You have in a leading article already indicated the limitations of the work of the Commission. It was appointed to determine as accurately as possible the expediency of purchase in the interests of ratepayers and water consumers on financial grounds, and with regard to the future as well as the present requirements of Water London. Now, Lord Balfour's Commission (1892–1893) reported in effect that the sources available within the watersheds of the Thames and Lee were adequate in quantity and quality for a period of 40 years from the date of the inquiry. Since that date the question of adequacy of supply at all times has been intensified and big schemes of increasing present resources or of tapping new water areas have been widely discussed, and to take Lord Balfour's Commission as an authority that was not to be gainsaid was an error. May not the London County Council take advantage of that error and try to re-open questions that have now been decided against them? The proposition by the London County Council to derive water from Wales was the most remarkable suggestion placed before Lord Llandaff's Commission. The London County Council has rendered excellent service to the metropolis, whatever may be said of its methods and ambitions, by forcibly attracting public attention to the important questions of transferring the water undertakings to a public body and of securing an adequate supply of pure water for all purposes.

I am, Sirs, yours faithfully,
MUNICIPALISATION.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Outbreak of Small pox and Measles in Bombay simul-
taneously with Plague.—The Plague in Karachi are
Poona.—General Decline of the Epidemic in India. The
Great Increase in Bombay City.—Inoculation then mak*and*
ndia, but

BOMBAY is not only in the commencement *in Bombay.*
epidemic of plague but it is confronted with a of a fourth
small-pox. The latter began to show itself abo n outbreak of
in the northern part of the city and three it a month ago
deaths numbered 36 In the week weeks back the
victims rose to 68 and for the nding Jan. 2nd the
the death-roll totaled 96. These week ending Jan. 9th
disease is spreading, and cases ar figures show that the
parts of the city. Up to the pre e now occurring in all
sent time the only other

regularly increased from 1876, the year when the organisation was founded, to 1896. From the beginning of 1897, when the service was reorganised, the expenses diminished by 72,000 francs in three years. In this period of time the receipts from patients who were visited at night amounted to 39,974 francs, making a total lessening in expenditure of nearly 112,000 francs. M. Vilain points out that even allowing for a fee of 10 francs for every night call during 1899 this sum represents a profit of at least 10,500 francs to the night medical service. This bonus will be added to the estimates for the year of the Exhibition—viz., 1900—the ordinary estimate being fixed at 145,000 francs. In the report submitted to the Municipal Council the balance sheet for 1899 was remarkable for a diminution in the expenses and an increase in the receipts. This happy result is owing in great part to a circular from the Prefect of Police, distributed at all the police-stations, which is handed to every person making a claim on the night medical service. The friends of the patient are informed that they must pay the fees owing to the collector for the district, gratuitous attendance being reserved solely for the very poor. This circular has certainly had the effect of cutting down expenses, and in one district, which formerly was noted for the calls made upon the night medical service, several persons after having been shown this circular have gone away without levying any further tax upon the service.

Hospital Laboratories.

In the recent debate upon the Budget at the Municipal Council M. Henri Rousselle, chairman of the Laboratories Department, again put forward a motion that the various private hospital laboratories should be suppressed and their place taken by a central laboratory for each hospital. M. Rousselle argued that this system would be much cheaper, as all instruments and apparatus could be used in common which are now dispersed among different laboratories whose separate upkeep is very little less expensive than would be that of a central laboratory. He said that culture stoves, autoclaves, and other apparatus could easily be used in common, and the laboratory would be under the charge of a director and two assistants who should be nominated by the medical staff of the hospital and chosen exclusively from among past house physicians and surgeons. The Municipal Council, which thinks of nothing but expense, accepted this view, but from the scientific point of view it has not been so favourably received by hospital medical officers. The work done in a medical laboratory is not comparable to that done in a commercial laboratory of which the Municipal Council was apparently thinking. The director of a medical laboratory is an actual collaborator personally associated with research, and it would be difficult for him were he to be associated with eight or ten different medical men engaged respectively in their own line of research, for he could not be equally versed in all of them. Also, in many researches the medical man engaged wishes his work kept secret before publication, which would be a difficult matter in a public laboratory. The view of a research laboratory current among the Municipal Council shows an absolute ignorance of the methods of scientific work customary in France. Even from the economic point of view the benefit is illusory. The present laboratories are carried on at but small expense and are quite sufficient for their present work. A central laboratory would need a large and specially constructed building and the expense of building would be a hundred times greater than the sum to be saved by a common use of apparatus. Also if, as would be the case, every medical man were to be engaged upon a research of his own his place would have to be reserved for him and so private laboratories would be practically reconstituted with the additional expense of new buildings for the public institution.

Influenza.

Influenza is raging in Paris as it is in every capital of Europe, and people are much exercised, for there is scarcely anyone who is not affected primarily or secondarily by the disease. Nevertheless, these fears are much exaggerated, for if the cases are numerous they are fortunately not serious. Dr. Bertillon, the head of the municipal statistical department of the city of Paris, in an interview on the subject declared that influenza, which is endemic in Paris, has this winter become particularly prevalent owing to the very damp state of the atmosphere. Here are the mortality figures from influenza during December and January. In December [illegible] deaths registered from [illegible] In January, 1899, there were 18 deaths, while in January, 1900, the figure rose to 39, and 20 of these occurred in the first week of the month, although the general mortality of Paris was not above the normal. The statistical department does not consider that a real epidemic exists—a view which, perhaps, has origin in the fact that a very severe epidemic was looked for during the winter of 1899-1900, based upon the fact that influenza made its appearance during the winter of 1889 and it was thought that there would be a special exacerbation after ten years' time. Such an opinion holds good for most epidemic diseases. The weather, however, continues unfavourable, the wind being constantly from the south. It must be remembered that the figures given above only represent deaths, but it is certain that the number of persons attacked is very large.

Feb. 6th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Influenza and the Holy Year.

LIKE the Horatian "pallida mors," influenza is knocking at the door of the hovel and at the portal of the palace. Queen Margherita is not spared by the unwelcome visitant any more than the subalpine peasant or the factory hand "in populous city pent." Her Majesty is now, I am happy to say, in full convalescence, though not yet allowed to leave her apartment, and the State concert fixed for to-day at the Quirinal has had to be postponed till that most shadowy of all periods, "a more convenient season." His Holiness the Pope "sta bene," I have just been assured; though certain changes in the "order of the day" at the Vatican are quite important enough for lay journalists to connect them with another "deliquio" or "raffreddore" on the part of Dr Lapponi's august patient. These "changes," it may be opportune to state, are thus accounted for: the pilgrimages which were to have started this week from Upper Italy have, by influenza, been so reduced in numbers that the "Commissione dei Pellegrinaggi per l'Anno Santo" has had to admonish their "personally conducting" bishops to defer them till their full complement can be made up. The Vatican, in so doing, is for once in harmony with the Italian Government, which sees in the influx of masses of poor people from disease-stricken communities a present danger for Rome, itself gravely visited by the same scourge. Even greater vigilance is being exercised at the French frontier in guarding against the introduction of infective maladies from that quarter. Not only influenza but small-pox is prevalent at Marseilles and Toulon; indeed, the latter disease has already found its way into Italy from those seaports. In view of the pilgrimages from France, therefore, the Italian Government has despatched to Ventimiglia, the frontier station, a fully equipped "servizio sanitario" to subject the pilgrims in question to a thorough examination, which is to exclude from Italy not only the influenza patient but also every individual not effectively vaccinated or revaccinated.

The Treatment of Influenza

While all the towns and villages are exposing in their churches the images of their respective saints or tutelary "patroni" and "patrone," and are, through their priests, preferring prayers for the removal or abatement of the influenza scourge, the medical schools are formulating the therapeutics hitherto found most efficacious in reaching the same end. The University of Turin, represented by one of its most authoritative consultants, publishes a series of practical indications for the benefit of the practitioner and of the more intelligent of the laity—indications not more significant in their positive than in their negative bearing on influenza. Practically, I may say, these correspond with the findings of the German Committee, which after the epidemic of 1890-92 obtained the opinions of 6000 medical men within the Fatherland as to their professional experiences in presence of the disease. Never, according to the Piedmontese professor, was there more need of the "medico" in contradistinction to "medicamenti" than in the influenza visitations of the last decennium. Yet, he says, "to day we have increased a thousand-fold the mania for phenacetine, salicylate of soda, salicylate of quinine, and such like," all this, moreover, because the lay or non-professional world sists on remedies which medical experience has either andoned or prescribes only in very special cases. This aving on the part of the public for "medicamenti" is couraged, he says, by those coöperative societies which vend their subscribers "boccette di chinina" (phials of quinine), boxes of phenacetine, or of the above-named salicylates thout professional sanction, till, with Dr. Furbringer (of e German Committee aforesaid), he finds that it is more than oubtful whether many patients are not suffering less from fluenza than from the "Galenical poisoning" induced by eir self-prescribed "medicines." Such "therapeutics" e greatly due to panic; and, if only to allay that epressing emotion, the patient who thinks he is "in for attack" cannot see the physician too soon and bring himlf under the sway of reason and clinical experience. *Au ste*, his indications are such as commend themselves British practice, in their attention to "small ings," in their consideration of every individual case "on s merits," in their avoidance of drastic agents, in their liance on rest in bed, above all in their warning against patience of the sick room or undue "haste to be ell" He would often, indeed, approve the line taken by a ell known English consultant who, when assured by his atient, "Doctor, I have tried everything," replied, "No, ou have not. Have you tried nothing?" and sent him back bed accordingly.

Feb. 5th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Bubonic Plague in New Caledonia.

THE bubonic plague has broken out at Nouméa, New aledonia, a port in regular communication with Sydney and nly three and a half days' distant. Immediately information eached Sydney of the occurrence of the outbreak the resident of the Board of Health took steps to have all essels arriving from New Caledonia placed in quarantine or 12 days. Several passengers were landed from the teamer *Pacifique* before the quarantine was declared. everal of them have been traced and placed under edical surveillance, but 10 adults and one child are still t large untraced. The steamer *Maroc* was also quarantined t Newcastle, but released on Dec. 29th. In August last he Government cabled to Dr Haffkine for a litre and a alf of his plague vaccine, but none has yet arrived, and r. Ashburton Thompson, the President of the Board of ealth for New South Wales, has recommended that the accine should be prepared locally in the laboratories of he Health Department. The late Government opposed he idea of giving the plague bacillus a home in any art of Australia, even under strict supervision, but probably he subject will now be reconsidered. In Queensland the overnment has ordered a quarantine of 14 days for all essels from New Caledonia. At Melbourne the *Australia* arrived with trans-shipped passengers from the *Pacifique*, and one passenger from Nouméa to Melbourne was placed in arantine and no other passengers were allowed to land. D [illegible] sswell, President of the Board of Health of [illegible] recommended that a supply of Haffkine's [illegible] ained from India At a special meeting of [illegible] ublic Health held on Dec. 30th, the following reso[illegible] agreed to

(a) T[illegible] hole of Polynesia, Madagascar, Seychelles Islands, and Reunion [illegible] be proclaimed as plague-infected.

(b) That [illegible] period of quarantining vessels from infected ports be 12 days, and that uniformity be urged upon New South Wales and the other colonies in this connexion.

(c) That the shipping companies affected be informed of the quarantine restrictions

(d) That the medical profession be asked to immediately notify the board and the councils of the householders concerned of any cases they discover, independent of the obligations imposed upon them by the Public Health Act

(e) That the Minister be asked to secure an immediate supply of the plague vaccine, as essential to the health of the community

(f) That the councils of the colony be informed by circular as to steps to be taken anticipatory of an outbreak

(g) That all vessels arriving from infected ports, whether they have been over the 12 days on the voyage without an outbreak on board or not, be inspected by medical officers for a week after arrival—i e, the second fourth, and sixth days of their stay at a Victorian port

(h) That no vessels from any Polynesian port be allowed alongside.

Annual Meeting of the Victorian Branch of the British Medical Association.

The annual meeting of the Victorian Branch of the British Medical Association was held on Dec 21st. The report of the council showed that the average attendance at the meetings during the year had been less than usual. The council had been forced to deal with several ethical cases, and in one had to expel a member for unprofessional conduct, the council's action being ratified by the branch. The following were elected as office-bearers for the ensuing year: President, Mr. G. A. Syme; vice-president, Mr F M. Harricks; treasurer, Mr. J. R M. Thomson; secretary, Dr. D. M. Officer; librarian, Mr. A. W. F. Noyes; Victorian editor of the *Australasian Medical Gazette*, Dr. J. W. Springthorpe; members of the council: Dr. A. V. M. Anderson, Mr. F. D. Bird, Mr. A. L Kenny, Mr. H. Lawrence, Dr. R. L McAdam, Mr. F. Meijer, Mr. M. U O'Sullivan, and Dr. R. R. Stawell. In his address the retiring president, Mr. A. L. Kenny, dealt almost exclusively with the internal affairs of the branch and its relations to the parent association, a subject on which he could speak with authority and knowledge, having acted for years as secretary of the branch and also subsequently as treasurer, and having represented the branch in England when visiting there. Mr. Kenny was of opinion that more interest should be taken in the affairs of the colonial branches by the council of the association and especially greater care and promptness exercised in the association's secretarial and financial dealings with the branch. The by-law of the association dealing with the election of colonial representatives on the council should be altered to permit a branch availing itself of the services of any suitable member who might be sojourning in London. At present a member of the council "must have resided within the area of the branch for at least 12 months prior to his election." Mr. Kenny next advocated the amalgamation of all the Australasian branches in one association as making for increased strength and influence in all Australasian public and professional matters in dealing with colonial Governments and in ethical questions. The amalgamation could also supply an effective and permanent managing body for the Australasian Medical Congresses. The fifth session of the congress at Brisbane was referred to in complimentary terms and some suggestions made for improvements in the routine of congress work, chiefly in the direction of giving more time to sectional work and less to entertainments. Mr. Kenny affirmed the propriety of the resolution passed by the congress with reference to hospital abuse. He recommended that hospital managers and medical officers should be legally empowered to recover fees from patients found guilty of imposition.

The New South Wales Nurses Association.

A special meeting of the New South Wales Trained Nurses Association was held on Dec. 1st to amend the constitution and rules of the association. The secretaries reported that the association numbered 227 members. It was resolved that the name of the association be altered to "The Australasian Trained Nurses Association" and the following was accepted as the basis for registration and membership:—

> Candidates for registration must produce proof—(a) That they have been engaged for three years in general hospitals recognised by the council and containing not less than 40 beds; or (b) that they have been engaged for four years in a country, district, or suburban hospital recognised by the council and containing not less than 20 beds and have been trained at that hospital under a matron or nurse who holds a certificate from a training school for nurses recognised by the council of this association, or (c) that they have been engaged for five years in a private, country, district, or suburban hospital recognised by the council, and containing not less than 10 beds, and have been trained at that hospital under a matron or nurse who holds a certificate from a training school for nurses recognised by the council of this association. Furthermore, all candidates must give references as to their moral character, produce certificates of competency from the hospitals in which they had been engaged, and account for any interval of time in their nursing career when not engaged in hospitals or nursing associations.

Fever Hospital for Sydney.

Dr. Ashburton Thompson, in his capacity as chief medical officer to the Government of New South Wales, has presented to Parliament a report on the need for a metropolitan fever hospital in Sydney. In his opinion such an institution is urgently required and is a necessary corollary to the notification clauses of the Public Health Act. It should not be removed to any great distance from the city. If a few acres of the Sydney Common on Dowling street could be obtained they would provide a suitable site.

Surgeons for South Africa.

Dr. A. MacCormick and Dr. R Scot Skirving of Sydney have volunteered and been accepted for service in South Africa.

Primary Sarcoma of the Liver in a Child 14 Weeks Old.

In the *Intercolonial Medical Journal* for December Mr. H. M. Hewlett records a case of primary sarcoma of the liver in a child 14 weeks old. The child's symptoms were diarrhœa and vomiting and in the abdomen was a swelling, extending from the costal margin to below the umbilicus, smooth and very tender. No jaundice was present. The swelling had appeared rapidly and rapidly increased. The necropsy showed that the swelling was an enlarged liver, studded with nodules which on microscopic examination consisted of large round cells and a few spindle and small round cells embedded in a delicate fibrillar matrix. The lungs were also studded with similar nodules. No other organs were affected. As far as Mr. Hewlett can ascertain the youngest case hitherto recorded was at 12 months.

Dec 28th, 1899.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following were admitted to degrees on Feb. 1st:—

Bachelor of Medicine.—F. Shufflebotham, Trinity; R. Ainsworth, Pembroke; G. S. Keeling, Caius; R. N. Salaman, Trinity Hall; and F. C. Eve, Emmanuel.

Bachelor of Surgery.—F. Shufflebotham, Trinity; O. Inchley and J. F. Skrimshire, St. John's; G. Browse and R. S. Trevor, Clare; and F. C. Eve and S. V. Pearson, Emmanuel.

FOREIGN UNIVERSITY INTELLIGENCE.—*Florence:* Dr. Angelo Mugnai has been recognised as *privat-docent* of Surgery.—*Halle:* The chair of Internal Medicine has been offered to Professor Kast of Breslau, but he has declined to migrate.—*Munich:* Dr. Otto Walkhoff of Brunswick has been appointed to the chair of Operative Odontology.—*Padua:* Dr. E. Truzzi of Messina has been appointed Professor of Clinical Midwifery in succession to the late Dr. Giovanni Inverardi.—*Pavia:* Dr. Casimiro Mondino of Palermo has been appointed Professor of Clinical Psychiatry.—*Rome:* Dr. Gaetano Mazzoni has been recognised as *privat-docent* of Surgery.

VACCINATION GRANT.—Mr. W. G. Evans, public vaccinator to the Second District of the Frome Union, has been awarded the Government grant for successful vaccination for the seventh time.

PROPOSED MUNICIPAL HOSPITAL FOR BARRY.—On Jan. 31st Dr. F. St. George Mivart of the Local Government Board conducted a public inquiry at Barry Dock into the application made by the Barry District Council for power to borrow £1800 for a site for the purpose of erecting a municipal general hospital for the town.

A PHILANTHROPIC MEDICAL MAN.—Dr. John Beddoe and his wife have provided six cottages as convalescent homes at Bradford-on-Avon where women and girls will be admitted for a nominal weekly contribution. The cottages have been comfortably furnished and fitted with modern sanitary appliances.

BRISTOL MEDICAL ATHLETIC CLUB.—The Bristol Medical Athletic Club held its annual meeting with the Birmingham Medicals at Bristol on Feb. 1st. The usual football match was played in the afternoon and resulted in a win for the home team. In the evening the visitors were entertained at dinner, Mr. J. Paul Bush being in the chair. A visit to the pantomime and a smoking-concert brought the day's proceedings to a successful close.

A MUNIFICENT BEQUEST.—The late Mr. S. Rudolph Zunz of Edgehill, Wimbledon, who died last December, has bequeathed £25,000 to one of the metropolitan hospitals, to be selected by his executors, in order to found and endow, as a memorial of his late wife, an "Annie Zunz Ward," in which is to be placed and kept in preservation a life-size photograph of her. The estimated value of Mr. Zunz's estate is £125,395, and after providing several annuities and assigning the aforesaid sum of £25,000 he directs that the surplus of the estate, the annuities as they fall in, and the entire residue, are to be appropriated to the founding and endowing of "Annie Zunz Wards," in such London hospitals as his executors may select, other than the hospital to which the above £25 000 has been allocated. For the "Annie Zunz Wards" it is considered that between £80 000 and £90,000 will eventually be available.

HOSPITAL SUNDAY IN BRISTOL.—Jan. 28th was observed as Hospital Sunday in Bristol and collections were made on behalf of the Fund in over 200 places of worship. In 1899 the sum of £1608 was contributed to the Hospital Sunday Fund.

PRESENTATIONS TO MEDICAL MEN.—Mr. E. F. Eliot, F.R.C.S. Edin., J.P., was presented on Jan. 25th with a plate-glass surgical instrument cabinet by Classes A and B of the London and South-Western, Southampton Dock, Branch of the St. John Ambulance Association as a mark of appreciation for his services as honorary lecturer of the classes.—Mr. Lennox Browne, F.R.C.S. Edin., has retired from the active staff of the Central London Throat and Ear Hospital but will continue to be identified with the institution as consulting surgeon. His colleagues on the committee and medical staff have presented him with an illuminated address recording their appreciation of his services to the institution since its foundation in 1874. Accompanying the address was a gift of old English furniture.

THE MANCHESTER MEDICAL GUILD.—The sixth annual meeting of the Manchester Medical Guild was held on Jan. 23rd, the President, Alderman F. H. Walmsley, J.P., M.R.C.S. Eng., being in the chair. There were 50 members present. The annual report of the council, which was received and adopted, stated that the council had held 14 meetings during the year and had dealt with many matters of professional interest, including club practice reform, hospital reform, advertising and "underselling," preliminary education, medical aid societies, direct representation on the General Medical Council, alleged secret commissions, the suggested Board of Conciliation, medical organisation, the International Congress of Medical Ethics at the forthcoming Paris Exhibition, district nursing, the collection of blood and other specimens for bacteriological examination for health authorities, points of etiquette, &c. Three members had died during the year, four had resigned, and 29 new members had joined—the number of members at date being 222. Special emphasis was laid upon the need of more localised organisation in order to carry out to the full the objects of the guild—every parliamentary division in the area covered should have at least one convener and every practitioner should be a member of the Guild.—The districts of Eccles and Harpurhey were held up as examples to be followed in this respect. The statement of accounts showed a balance in the bank of over £37. The election by the council of the president (Mr. Walmsley) and of the following honorary vice presidents was approved:—Dr. Henry Ashby, Dr. C. H. Braddon, Dr. Samuel Buckley, Mr. Wm. Crosby, Dr. J. Dreschfeld, Dr. A. M. Edge, Dr. C. E. Glascott, Dr. Alfred Godson, Dr. James Hardie, Mr. Francis Hepworth, Mr. Thomas Jones, Dr. David Little, Dr. J. Dixon Mann, Dr. D. Lloyd Roberts, Dr. Henry Simpson, Mr. F. A. Southam, Dr. Graham Steell, Mr. Walter Whitehead, Dr. Sam Woodcock, Mr. G. A. Wright, and Mr. A. H. Young. The following officers and council were elected:—Chairman: Mr. Geo. Arthur Wright. Vice-chairman: Mr. R. H. Wolstenholme. Honorary treasurer: Dr. C. G. L. Skinner. Honorary secretary: Dr. Arnold W. W. Lea. Ordinary members of council: Mr. Samuel Bagley, Dr. Isaac Blore, Mr. William G. Booth, Mr. G. H. Broadbent, Dr. Alfred Brown, Dr. Samuel Crawshaw, Dr. Alexander Fraser, Dr. John H. Godson, Dr. William Graham
Dr. J. Wilson Hamill, Dr. John C. Nichol, Mr. Davi
Owen, Mr. Alic Phillips, Dr. J. Ratcliff-Gaylard, Dr. A
Brown Ritchie, Mr F. Leyland Roe, Mr. Arthur W. Senio
Dr. Alexander Stewart, Mr. J. W. A. Wood, and Dr. F. H
Worswick. Auditors: Dr. J. Stavely Dick and M
J. W. Moore.

NOTES ON CURRENT TOPICS

The Midwives Question.

THE Bill promoted by private members "to secure the better tra
of midwives and to regulate their practice" was introduced int
House of Commons on Friday, Feb 2nd, by Mr. TATTON EGE
The names on the back of the Bill on this occasion are those
introducer, Sir WILLIAM HART DYKE, Mr. SCHWANN, Mr. H
Mr. HEYWOOD JOHNSTONE, Mr BONSOR, Mr. FLOWER and Mr. TE
In the ballot for places Mr. TATTON EGERTON drew the eighth

which enabled him to put down the second reading of the measure in the second place on Wednesday, Feb 28th As the measure in the first place on this day is the Mines (Eight Hours) Bill—a measure certain to give rise to a long debate—it is improbable that the Midwives Bill will be reached in time for discussion

Bills Introduced

On Monday, Feb 5th, in the House of Lords, the Lord Chancellor introduced the Lunacy Bill promised in the Queen's Speech, and the Earl of Lichfield a Bill to amend the Isolation Hospitals Act of 1893. No date has been fixed for the second reading of either Bill

Vaccination Petition

When Members of either House present petitions it is not to be taken that they necessarily agree with the views expressed in them. The Lord Chancellor was careful to explain this when on Tuesday, Feb 6th, he presented a petition from the guardians of Wandsworth and Clapham Union in favour of an amendment of the vaccination law so as to prevent vaccination officers from prosecuting defaulters without first obtaining the sanction of the guardians His lordship carried his explanation so far as to say that he entirely disagreed with the prayer of the petition

HOUSE OF COMMONS

THURSDAY FEB 1ST

Inoculation with Anti Typhoid Serum.

Mr **ALFRED PEASE** asked the Under Secretary of State for War if the War Office had sanctioned the experiment of inoculating with anti typhoid serum troops now on their way to the front, and if, in view of the uncertainty that exists as to the efficacy of inoculation as a preventive of enteric fever, and the debilitating effects of the operation, the Department would forbid the continuance of these experiments, and whether his attention had been drawn to the description in the *Morning Post* of Jan 29th of the condition and appearance of the soldiers who had submitted to the inoculation on board the *Dunottar Castle*.—Mr **WYNDHAM**: The efficiency of the treatment appears to be sufficiently well established to justify the continuance of this operation, which is voluntarily submitted to by the troops

FRIDAY, FEB. 2ND.

Street Noises

On the motion of Mr **JACOBY**, a Bill was introduced at this sitting to control and regulate street noises

Meat for the Troops

General **LAURIE** and Mr **JEFFREYS** addressed questions to the Secretary to the Admiralty with reference to the quality of the fresh meat supplied for the use of the Royal Artillery and other troops taking passage on the steamship *American* which sailed from Southampton for South Africa in the month of January.—Mr **MACARTNEY** replied Arrangements were made with the owners of the *American*, the West Indian and Pacific Steamship Company (Limited), to victual the troops at the rate of 1s per head per day A portion of the troops embarked at Southampton and it has been reported that the fresh meat in question, on being put on board at Southampton, was at once rejected by the embarking officers at the usual inspection of provisions on the ground that it consisted entirely of "bull" and old cow "beef The day being Sunday a fresh supply could not be obtained at that port but in accordance with telegraphic instructions it was replaced at Queenstown (where the remainder of the troops embarked) by meat of good quality ordered by the owners' agent at their expense The owners state that the meat was purchased from a firm who they are informed, have supplied a large number of transports and two important trans oceanic passenger lines The full market price was paid for it, a guarantee having been given that it would give satisfaction. The contractors state that some of it had been served in the saloon and also to the troops before it was condemned without a word of complaint and that after the meat was returned it was inspected by the town doctor, who certified that it was perfectly sound, it being afterwards disposed of to his family and hotel customers The directors of the steamship company gave instructions that the victualling of all transports was to be done with unstinted liberality and regardless of cost.

MONDAY, FEB 5TH

Sanitation of Gibraltar

Mr **CHAMBERLAIN**, replying to a question addressed to him by Mr **STEVENSON** said that the health of Gibraltar was good The death-rate for 1898 was only 17·79 per 1000 The remodelling of the whole drainage of the fortress was concluded early last year and he had no reason to believe that anything further was required The Sanitary Commissioners had already sufficient powers for dealing with insanitary houses and were exercising them satisfactorily There was no space available on the limited part of the Rock not reserved for military purposes for the provision of further recreation grounds nor so far as he was aware had any recommendation been made to that effect

Medical Certificates in the Post Office Service

Mr **STEADMAN** asked the Secretary to the Treasury as representing the Postmaster-General, whether he was aware that a female telegraphist of the Western District office London, visited Dr Mason, the official medical officer, on Dec 18th 1899, who, whilst admitting she was suffering from a severe cold, stated that she could perform her duties; that on the same day Mr Oswald of Brixton, who had been in attendance on the telegraphist for some time, certified she had bronchial catarrh and debility and ordered her to remain indoors and that although Mr Oswald afterwards extended the certificate till Dec. 28th the telegraphist had been reported and punished with the loss of two days pay for remaining from office during this period, whether it could be stated why the Post Office medical official declined to accept the certificate of a well known practitioner, and whether the Postmaster-General would personally investigate the circumstances which had led to the telegraphist being condemned for malingering though only acting in obedience to medical instructions.—Mr **HANBURY**: In the opinion of the medical officer of the Western district, who saw the telegraphist in question on the 18th and 23rd of December, her state of health on those days was not such as to require her to remain at home, but as Mr. Oswald, who saw her on the 28th, was of a contrary opinion, the Postmaster General had thought it right to give her the benefit of the doubt and her pay for the two days in question has been allowed.

The Case of the Transport "Jelunga"

In reply to a question on this subject by Mr Swift MacNeill Mr **WYNDHAM** said About 500 wives and children of soldiers were landed from the transport *Jelunga* They were not in a destitute condition, but they were in a very neglected condition, owing to the want of a sufficient staff on board to look after them It would no doubt have been difficult for the general officer commanding at Cape Town to provide a sufficient staff but the Secretary of State for War is of opinion that proper care was not taken, and a reprimand has been accordingly sent to Cape Town No nurse was on board Six children died in the course of the voyage; they did not die of cold and exposure since they died in the tropics The women were periodically asked throughout the voyage whether they had any complaints to make, and they made none on the subject of their accommodation The staff officer at Southampton and the officer of the Soldiers and Sailors' Families Association made every effort to help the women on their arrival, all were asked if they wanted money and all said that they had it. Ten women and 35 children had to spend the night at Waterloo. I have answered this question at length because the Secretary of State regards the incident as most regrettable and is anxious that it should be fully explained to the House As I have said, care has been taken to impress upon those concerned the necessity of avoiding such mistakes in future

TUESDAY, FEB 6TH

The Strength of the Army Medical Service.

Sir **WALTER FOSTER** asked the Under Secretary of State for War how many officers of the Royal Army Medical Corps are now employed in South Africa and how many civil medical officers have been sent out to aid them, how many officers of the Royal Army Medical Corps are employed at other foreign stations and how many are at home stations, and whether it is intended to employ any of the retired pay officers for duties in the United Kingdom.—Mr **GEORGE WYNDHAM**: 308 officers of the Royal Army Medical Corps are employed in South Africa 377 at other foreign stations and 111 at home 133 civil surgeons are employed in South Africa and 28 more are under orders to go 112 retired pay officers are employed at home

PRESERVATIVES AND COLOURING MATTERS IN FOOD

EVIDENCE BEFORE THE DEPARTMENTAL COMMITTEE.

MONDAY, FEB 5TH

THE Committee appointed by the President of the Local Government Board to inquire into the question of preservatives and colouring matters in food held another meeting to day, at the rooms of the Chemical Society, Burlington House and proceeded with the collection of evidence The Committee consists of Sir Herbert Maxwell, M P, chairman Professor Thorpe Dr Bulstrode and Dr Tunnicliffe, with Mr O J Huddart, Secretary

Dr **BLAXALL**, lecturer on bacteriology in the Westminster Hospital Medical School and bacteriologist to the Vaccine Department of the Local Government Board, examined by the chairman, said that he had undertaken experiments dealing with the bacteriological action of preservatives in milk His first idea was to see whether small quantities of formalin could be used to sterilise milk and whether the formalin could be driven off leaving the milk sterile but this he found to be impossible. He found that it required 1 in 500 of formalin to effect sterilisation in milk This strength killed all germs in the milk and made it keep indefinitely He had milk with 1 in 500 of formalin which had kept for seven months The milk with which he experimented was bought from local dealers in London and was received not in sterilised vessels but in ordinary domestically cleaned vessels from which it was measured out in known quantities He tested all the samples for formalin, but he only tested the first two for boric acid or salicylic acid. The bacteriological test which he applied to the control milk showed that it was in a normal condition The samples were kept hermetically sealed With one exception all the controls went bad in 24 hours the exception occurring on a very cold night. The experiments he had made with boric acid proved that this was a much less powerful germicide or even antiseptic than formalin. Boric acid would not sterilise milk in any of the proportions he used, and he used as much as 1 in 33, the milk would only take up 1 in 25. The proportion of 1 in 33 prevented fermentation, but did not prevent germs being in the milk

By Professor **THORPE** His experiments were all made with commercial milk in the condition in which it would be supplied to the consumer, and the bacteriological examination of the control samples showed, with certain exceptions that the samples were taken comparatively near milking time. Salicylic acid he found to be as little efficacious as boric acid His experiments were made from the point of view of a scientific man—to study the course of the action of preservatives upon the milk—and he did not attempt to imitate the conditions in which these preservatives might be used in the practice of trade He had general but not expert knowledge of the conditions in which they were used commercially and he could not say whether such an amount as 1 in 600 of formalin was ever used His experiments had shown that 1 in 10 000 of formalin would keep milk sweet for a short time—for possibly 24 hours—at 60° F He had not found it keep for 24 hours at 80° F He quite agreed that want of precise information as to the age of the milk caused a considerable amount of uncertainty as to the direct applicability of his results

Professor **THORPE**: Would you say from your experiments that 1 in 50 000 of formalin would be of any use in keeping fresh milk sweet for 24 hours on a hot day?

Dr **BLAXALL**: It entirely depends upon what comes in contact with fresh milk If fresh milk is sterilised then it does not matter whether you put in formalin or not.

Professor **THORPE**: But suppose ordinary commercial conditions, do you think 1 in 60 000 of formalin would be of any practical use in keeping fresh milk sweet for 24 hours in hot weather?

Dr **BLAXALL**: I do not think it would be of any use

In answer to further questions by Professor **THORPE**, Dr **BLAXALL** said that in his experiments quantities like 1 in 2000 of boric acid and 1 in 50,000 of formalin had no material effect in keeping milk sweet, though of course they had a certain effect.

By Dr. TUNNICLIFFE: From a bacteriological standpoint a commercial milk containing from 200 to 500 organisms per loopful would be a fair normal milk. It was difficult to say what number of organisms would render the milk unsaleable, because everything depended on the kind of organisms present. In the summer he bought two samples of milk and they contained 20,000 and 40,000 organisms per loopful and there was no evidence that the milk was sour or unfit for sale. The probability was that the greater the number of organisms the nearer the milk was to sourness and therefore to decomposition. In some of these milks to which preservatives had been added, say boric acid, there was still an innumerable amount of organisms and yet the milk had not gone bad; fermentative action had been stopped but other organisms had been allowed to grow. He was not prepared to give an opinion upon the antiseptic action of these preservatives from the point of view of their toxic equivalents.

By Dr. BULSTRODE: The formalin he used in his experiments was a 40 per cent. solution. He commenced to work in May and went on through May and June, then in a desultory fashion in August, and then he commenced again in September, and all through the autumn and winter he had been working at the subject systematically. It was quite obvious that besides lactic acid changes there were other changes which might be going on in the milk. They were nearly all distinguishable by smell; he did not think that the milk would be sweet if processes which were deleterious were going on. He thought that pathogenic organisms, such as the typhoid bacillus, might be expected to be inhibited by less quantities of the preservatives than would be required for the complete sterilisation of the milk, for the typhoid bacillus was much less resistant than the lactic acid bacillus.

Mr. HENRY CHARLES CAMERON, Produce Commissioner for the Government of New Zealand, the only other witness examined at this sitting of the Committee, gave evidence principally with regard to the New Zealand butter trade. He explained that the Government of the colony seek to improve the industry by means of instruction and inspection and that their efforts in these directions are eminently successful. The bulk of the New Zealand butter sent to this country was, he said, either treated with salt or with a preservative whose basis was boric acid. It was found necessary to use this preservative because, according to Mr. Cameron, butter which had been brought to this country in refrigerating chambers deteriorated more rapidly when taken out of these chambers than butter which had not been frozen. But the quantity of preservative required was small, not more than one half per cent. Mr. Cameron thought that there should be a statutory limit and he suggested half per cent. as suitable in the case of butter.

The Committee then adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ADAMS, JOSEPH DIXON, M.D. St. And., M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health by the Yeovil Rural District Council.

AMBROSE, A. P., M.R.C.S., L.R.C.P., has been appointed Clinical Assistant to the Chelsea Hospital for Women, Fulham-road, London, S.W.

ANDERSON, F. T., M.D. Brux., F.R.C.S. Edin., has been appointed Honorary Medical Officer to the Barnstaple and North Devon Dispensary, vice J. L. W. Ware, resigned.

BEGGS, J. B., B.A., M.D., D.P.H. Cantab., has been appointed Medical Superintendent to the Grove Fever Hospital, Tooting, S.W.

BIRKETT, G. T., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Catford Sanitary District of the Lewisham Union.

GREENWOOD, T. PARKER, M.B., C.M., B.Sc. Edin., has been appointed Assistant Medical Officer to the Three Counties Asylum, Hitchin.

GRIFFITHS, JOHN, L.R.C.P. Lond., M.R.C.S., has been appointed District Chief Superintendent of the No. 2 District (Southern and Western Counties of England and Wales) of the St. John Ambulance Brigade.

JONES, W. WATKINS, M.D., C.M. Edin., D.P.H. Camb., has been appointed Medical Officer of Health to the Gelligaer and Rhigos District Council.

MANDER, PERCY ROBERT, L.R.C.P. Lond., M.R.C.S., L.S.A., Deputy Medical Officer of Dartmoor Prison, has been transferred to Wandsworth Prison, and will be succeeded at Dartmoor by Mr. Forward.

METCALFE, G. E. GIBSON, L.R.C.P., L.R.C.S. Edin., L.F.P. Glasg. & L.M., has been re-appointed Medical Officer for the Capel District of the Tonbridge Union.

MORGAN, FREDERICK CHARLES, L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer at the Eastville Workhouse by the Bristol Board of Guardians.

NOBLE, H. PERCY, M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed Assistant Anæsthetist to the Middlesex Hospital.

PASTEUR, WM., M.D. Lond., F.R.C.P., M.R.C.S., has been appointed Physician to the Middlesex Hospital.

PORTER, CHAS., M.D. Irel., M.R.C.S., D.P.H. Cantab., has been appointed Medical Officer for the County of Salop.

POTTS, W. J., M.D. Lond., L.R.C.P., M.R.C.S., D.P.H. Camb., has been appointed Medical Superintendent of the Infirmary, parish of St. Matthew, Bethnal Green, London.

RENSHAW, C. A. K., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Aston-on-Mersey Sanitary District of the Bucklow Union, vice J. Paulin, resigned.

RICHARDSON, R. J., M.B., C.M. Edin., has been appointed Visiting Physician for the Netherfield-road Hospital, Liverpool.

RISDON, GEORGE OWEN, L.R.C.P. Lond., M.R.C.S., L.S.A., has been re-appointed Medical Officer for the No. 2 District of the Wells (Somerset) Union.

ROBINSON, ARTHUR HENRY, M.D. Durh., M.R.C.S., D.P.H. Camb., has been appointed Medical Superintendent of the Islington Infirmary, Highgate-hill, N.

ROSSER, J. S., M.D. Glasg., D.P.H. Glasg., has been appointed Medical Officer for the Llandovery District of servants employed on the London and North-Western Railway, and also Medical Officer to the railway employés of the Llandovery and district Railway Medical Fund, vice F. W. Lewis.

ROWBOTHAM, A. J., M.R.C.S., has been re-appointed Medical Officer for the Newton-on-Trent Sanitary District of the Gainsborough Union.

ROW, C. M., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Fourth Sanitary District of the Battle Union, vice J. C. Garman, resigned.

SHARPLEY, J. E., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer for the Blyborough Sanitary District of the Gainsborough Union.

VINCENT, R. H., M.B., B.S., has been appointed Clinical Assistant to the Chelsea Hospital for Women, Fulham-road, London, S.W.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

ALDERSHOT URBAN DISTRICT COUNCIL.—Medical Officer of Health. Annual election. The inclusive salary will be £300 per annum payable quarterly.

BATH GENERAL OR ROYAL MINERAL WATER HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and apartments in the Hospital.

BRECON INFIRMARY, South Wales.—Resident House Surgeon, unmarried. Salary £90 per annum, with furnished apartments, board, all found except beer, attendance, fire, and gas.

BRISTOL EYE HOSPITAL.—House Surgeon. Salary £120, without residence.

BURTON-ON-TRENT INFIRMARY.—House Surgeon. Salary £150 for the first year and £170 for the second year, with furnished rooms in the Infirmary, and coals and gas free.

CARDIFF INFIRMARY.—Assistant House Surgeon and Assistant House Physician, each for six months. Salaries at the rate of £50 per annum, with board, washing, and apartments.

CHELSEA HOSPITAL FOR WOMEN, Fulham road, S.W.—Clinical Assistant. Tenable for three months on payment of eight guineas.

CITY ASYLUM, Nottingham.—Second Assistant Medical Officer, unmarried. Salary £150, with board, apartments, and washing.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY, Dumfries.—Assistant House Surgeon. Board and washing provided.

DUNDEE ROYAL INFIRMARY.—Fourth Resident Medical Assistant for six months. Salary at the rate of £40 per annum, with board and washing.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, London.—Surgeon to Out-patients.

GENERAL HOSPITAL, Nottingham.—Assistant House Physician for twelve months. Salary £50, with board, lodging, and washing in the hospital.

GENERAL INFIRMARY AT GLOUCESTER AND THE GLOUCESTERSHIRE EYE INSTITUTION.—House Surgeoncy. Salary £100 per annum, with board, residence, and washing.

GLASGOW LUNACY DISTRICT BOARD.—Medical Officer (Assistant) for Woodilee Asylum, to act as Pathologist. Salary £100 per annum, with board, apartments, &c.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway road, London.—Assistant Anæsthetist for six months. Honorarium at the rate of 10 guineas per annum.

HANTS COUNTY ASYLUM, Fareham.—Third Assistant Medical Officer, unmarried. Salary £125 per annum, increasing to £150 after twelve months' service, with furnished apartments, board, washing, and attendance.

HASTINGS, ST. LEONARD'S, AND EAST SUSSEX HOSPITAL.—House Surgeon, unmarried. Salary £75 per annum, with residence, board, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormonde-street, London.—Two House Surgeons to Out-patients, for six months. Salary 25 guineas each.

HULME DISPENSARY, Dale-street, Stretford road, Manchester.—House Surgeon. Salary £130 per annum, with apartments, attendance, coal, and gas.

INFIRMARY OF THE WANDSWORTH AND CLAPHAM UNION, St. John's-hill, Clapham-junction, S.W.—Third Assistant Medical Officer for twelve months. Salary £70 per annum, with board, lodging, and washing.

KENT AND CANTERBURY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £50 a year, with board and lodging.

KENT COUNTY OPHTHALMIC HOSPITAL, Maidstone.—House Surgeon. Salary £100 per annum, with board and lodging in the Hospital.

KING'S COLLEGE, London.—The Sambrook Medical and Surgical Registrarships (open to King's College students only).

LIVERPOOL NORTHERN HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with residence and maintenance in the house.

LONDON COUNTY ASYLUM, Hanwell.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing.

MERCER'S HOSPITAL, Dublin.—Vacancy on the Surgical Staff.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Assistant Physician and Pathologist, Surgeon for Diseases of Women, and an Assistant Surgeon.

MIDDLESEX HOSPITAL, W.—Assistant Physician.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road.—Junior Resident Medical Officer for six months. Salary at the rate of £40 per annum, with board, attendance, and washing.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon. Salary £140 per annum, all found except board, unmarried.

Royal Hants County Hospital, Winchester —House Surgeon, unmarried Salary £65 per annum, rising to £75, with board, residence, &c.

Royal Sea Bathing Hospital, Margate.—Resident Surgeon Salary £100, with board and residence Apply to the Secretary, Royal Sea Bathing Hospital Offices 30, Charing-cross, London

Salford Royal Hospital.—House Surgeon for twelve months Salary £100 per annum, with board and residence

St Thomas's Hospital.—*Vacancy for a Physician*

Seamen's Hospital Society (*Dreadnought*) Greenwich —Senior House Surgeon Salary £75 per annum, with board and residence and an additional £25 per annum conditionally Also House Surgeon Salary £50 per annum, with board and residence. These vacancies are for Officers at the Branch Hospital in the Royal Victoria and Albert Docks

Stockport Infirmary —Junior Assistant House Surgeon for six months Salary £2 per mensem, with residence, board, and washing

Surrey Dispensary, Southwark S E —Physician Honorarium 50 guineas per annum

Tottenham Hospital.—Honorary Physician to In patients

Ventnor Royal National Hospital for Consumption and Diseases of the Chest —Assistant Resident Medical Officer Salary £100 per annum Apply to Dr Parry, R M O

Western Dispensary, Rochester row, Westminster —Resident Medical Officer, unmarried Salary 100 guineas per annum, with furnished rooms, coals, gas, and attendance.

Western General Dispensary, Marylebone-road, London.—House Surgeon, unmarried.

West Bromwich District Hospital.—Resident Assistant House Surgeon —Salary £50 per annum with board, &c

West Kent General Hospital, Maidstone —Assistant House Surgeon for six months Honorarium at the rate of £60 per annum, with board and residence.

Western Ophthalmic Hospital, 153 Marylebone-road, London.—Assistant Surgeon

Worksop Dispensary Hospital.—Resident Surgeon, unmarried Salary £120 per annum, paid monthly, with increase when hospital is opened Rooms, coal, gas, furniture, and house keeper provided Apply to Mr Charles A Whall, Worksop

Births, Marriages, and Deaths.

BIRTHS.

Daman —On Feb. 6th, at Oakhurst, Dorridge, Knowle Warwickshire, the wife of Karl A. Daman L D S, of a daughter

Kirkby —On Feb 5th, at Maesteg Glamorganshire the wife of Walter Kirkby L R.C P Edin, L.R.C S Edin, of a daughter

Ross —On Jan. 29th, at Burslem, Staffordshire the wife of William Levingston Ross, L.R.C S & L.R.C P I, of a son.

Wingfield —On Feb 3rd at Winchester, the wife of Hugh E Wingfield, M D, of a daughter

Young —On Jan 26th at Hunmanby Yorks, the wife of Charles A. Young B A. Cantab, M R C S, L.R.C P, of a son

MARRIAGES

East—Triggs —On Feb. 3rd at Holy Trinity, Bishops road, Paddington, by the Rev Edwin Allwright, M.A., William Norwood East, M.B Lond, M R.C.S, L R.C P, of Portland, Dorset, son of W Quartermaine East, to Linnie, only daughter of Mrs. Triggs of 133 Westbourne-terrace, W

Stabb—Huntley —On Feb 5th at the Church of SS Philip and James, Cheltenham, William Wilking Stabb, M D, of Torquay, to Mary Gertrude, only daughter of the Rev Osmond C Huntley, of Boxwell Gloucestershire.

Warden—M Kendrick —In the Bute Hall University of Glasgow, on Saturday Feb. 3rd, by the Very Rev Principal Story, D D and the Rev Joseph Vickery Castle-street Congregational Church Dundee (uncle of the bride), Archd A. Warden, M A M D Paris, to Rachel Mary, elder daughter of John Gray M'Kendrick Professor of Physiology in the University of Glasgow At home after 20th curt., 60, Avenue d Jena, Paris

DEATHS.

Adams.—On Feb 3rd at Loudoun-road N W, William Adams, F R C S aged 80 years.

Grainger Stewart —On Feb. 3rd at Charlotte-square, Edinburgh, Sir Thomas Grainger Stewart, M.D, LL.D, Physician in Ordinary to Her Majesty the Queen in Scotland, and Professor of The Practice of Physic in the University of Edinburgh

Maxwell.—On Dec. 30th, 1899, at Wahroonga, Sydney New South Wales, Charles Mayne Maxwell, M.B, M.R.C S, lately of Lasswade, Midlothian

Myddelton Gavey —On Feb 4th at 16, Broadwater Down, Tunbridge Wells after influenza, Frances Caroline, the dearly loved wife of E. H Myddelton-Gavey M R C S Eng, and daughter of the late Charles Catt of Summerhill, Lindfield aged 41 years

Oakeley —On Feb 4th at Lydart, Pepys road New Cross S E, Charles Edward Oakeley, L.R.C P, L R C S Edin, & L.M, L F P S. Glasg

Turner.—On Feb. 2nd, at St Leonard's, Frank Charlewood Turner, M.D, F R.C P Physician London Hospital, of Warren Wood, Wrotham, Kent.

Wellborne.—On Feb. 2nd, at Brixton, Richard Wellborne, M.D, in his eighty fifth year

N B —A fee of 5s. is charged for the insertion of Notices of Births, Marriages or Deaths.

Notes, Short Comments, and Ans
to Correspondents.

THE MEDICAL PROFESSION IN ENGLAND FROM A
POINT OF VIEW

We have received a French paper—by name *La Parfait Nourri*
February 1900, containing an article entitled ' Les Médecins
Comment ils exercent leur Profession," by Dr Edouard M
The article is amusing and as being the view of a foreigner
a note of some of its more salient passages will interest ou
Dr Montholon commences by pointing out that in ev
country but England the word 'shop and doctor
are in direct opposition and are only combined when it is
insult the profession It is otherwise in England where t
compares with an ordinary tradesman, whom he further rese
selling medicines Dr Montholon gives an amusing descri
"sixpenny practice, but we think he is a little too gener
estimate that such a practitioner may be found in one stre
five He visited many and says "The consultation took f
to five minutes, rarely more and the form of question wa
the same 'Where do you feel bad? What do you com
How long have you been ill? Do you drink?' The answe
the assistant scribbles a prescription chooses a medicine
made up from some within reach of his hand and gi
the lot to the patient mentioning his fee Next
Including the medicine the consultation costs one
shillings and very rarely more than three francs e
the case of a dressing or of an operation We cannot
whether this paper is only one of a series of articles or w
is meant to be a picture of the universal state of medical
in England, but we should fancy that the former was the ca
picture of the state of opinion among a certain class of pati
overdrawn when he says: Public confidence is given to a med
who has lots to do rather than to a man of science and tale
chief practitioners at the large hospitals, or to the learned an
members of the profession. In London men such as Pasteur,
Velpeau, and Pean are considered as amateurs and not as seri
titioners. Sir Joseph Lister and Sir James Paget are much les
than a *rebouteux de faubourg* who sees 200 patients a wee
shop" Then comes the following amazing piece of info
"At the most a cobbler would allow himself to be treate
William Jenner, baronet and physician to the Queen, becau
beginning of his career he *was employed for 10 years in a d*
shop in Albany street and five years in a 'doctor's shop' a
stead' It is well known that when a very young man the
William Jenner had his own way to make. We hardly fan
ever, that this was how he gained the confidence of the
class It must not be supposed that Dr Montholon writ
condemnatory spirit. On the contrary, he bewails the re
measures which prevail in France There of course, no med
is allowed to sell medicines and therefore, according to D
tholon, half the practitioners are perishing from hunger

THE SLAUGHTER HOUSES IN ALDGATE HIGH STRE

Many medical men, especially *those whose student days wer*
at St. Bartholomew's or the London Hospital will rec
picturesque if somewhat odoriferous, row of some 15 b
shops in Aldgate High-street. Behind them were slaughter
the *operations* in which were very fairly visible from the st
which though *necessary*, were neither edifying nor pleasant.
of the shops the gutters often ran with blood and altoget
establishments were thoroughly out of place in a large city
from the *City Press* that a motion for their abolition is to be
forward at a near meeting of the Common Council An
archæologist might hope *that the buildings will be left,*
are interesting *specimens* of architecture and there is none t
of Old London left, but for the abolition of the trade
carried on we have nothing but praise

' THE MACKEY FUND

medical advertising by a firm of chemists carrying on busi
19, North Earl-street Dublin and on Nov 4th (page 1275) we
a letter stating that the same address was given in the
Register and Medical Directory as that of a Mr J C. Mc
L.R.C S I and L.A.H Our correspondent made the rema
perhaps Mr McWalter could offer some explanation, an
stated that the Royal College of Surgeons in Ireland has
to give him an opportunity

"IMPROPER ADVERTISEMENT."

To the Editors of THE LANCET.

SIRS,—Referring to the letter published by you in your issue of the 23rd of December, 1899 (page 1790), in which a correspondent made a charge of improper advertisement against me, and referring to the letter from me to you, published by you in your issue of the 30th of December, 1899 (page 1870), informing you that the statements contained in the said letter signed "Ethics" were absolutely untrue, I was advised to commence an action for libel against you in respect of the false statements which you were led through your correspondent to make against me. In view, however, of the fact that you have in your issue of the 3rd inst. (page 355) unreservedly withdrawn all the imputations made upon me in the said letter of your correspondent and apologised for making the same and have done everything in your power to make reparation to me for the injury you have done me I am prepared to accept the apology which you have made and so end the matter. I may add that my only object in prosecuting the action was to absolutely clear myself from any imputation made against me, and this having been done I am satisfied.

I am, Sirs, yours faithfully,

Harley-street, 7th Feb., 1900. KARL FÜRTH.

PROFESSIONAL UNION.

WE have always maintained that for redressing the grievances and improving the position of the medical profession no course of action affords such hopeful prospects of success as the cultivation of a fraternal spirit. Wherever disunion prevails there will be no lack of patients and others ready to take advantage of the conditions imposed by the overcrowded state of the profession and to obtain the services of medical practitioners on terms incommensurate with the outlay of money and time which has been incurred in their education and acceptable only to the necessitous. No further illustration of this is required than the fact that associations exist by means of which large populations, not necessarily of the poorest, can obtain medical attendance for a payment of 2*d.* per week or less. For this reason we were glad to be able to make the announcement of the formation of the Birmingham and District General Medical Practitioners' Union (THE LANCET, Dec. 30th, 1899, p. 1866), a list of the officers of which will be found in THE LANCET of Jan. 27th, p. 278. A statement issued by the three joint honorary secretaries explains that the union has been formed during the last few months and has been constituted on thoroughly democratic lines, giving every practitioner an opportunity of bringing forward his individual opinions in a constitutional manner and securing united action of the local profession through direct representatives. The area included in this organisation is that which is known as "Greater Birmingham," extending on all sides to some five miles from the centre of the city, and has been divided into 14 medical wards. The members in each ward are invited to elect representatives who form a central council for conducting the actual business of the union. Already nearly 200 members have been enrolled, including men in every grade of general practice, and the moving spirits of the organisation expect that when it is completed it will gain the support of all practitioners who have at heart the welfare of their profession. The union is not intended to compete with existing medical societies or associations and will be limited entirely to medico-political and medico-ethical matters. Its objects are defined to be (*a*) to provide an effective organisation for the purpose of dealing with all matters affecting the interests of general practitioners; (*b*) to promote union and good-fellowship amongst neighbouring practitioners; (*c*) to endeavour to establish, as far as possible, an improved scale of fees; (*d*) to discourage advertising of every kind and other unfair and unprofessional competition; (*e*) to promote more satisfactory relations between the different branches of the profession; (*f*) to consider and take action upon all legislative proposals calculated to affect the interests of general practitioners; (*g*) to endeavour to obtain increased representation for general practitioners on the General Medical Council and other public bodies; (*h*) to endeavour to remedy, as far as possible, the abuses of hospitals and dispensaries; (*i*) to establish a medical club house, with such accommodation as may be considered desirable for the purposes of the union; (*j*) to provide facilities for the collection of members' accounts; and (*k*) to oppose any attempt on the part of public bodies to exploit the services of any member of the profession to the detriment of the others. The scope of this laudable programme is obviously a very large one and will require considerable business capacity on the part of those who may be charged with carrying it into execution, but where is that talent to be found if not in Birmingham? Above all things it must be remembered that comparatively little can be accomplished without unanimity, and for this reason it is to be hoped that the new association may receive hearty support from those whose interests it seeks to protect. Medical practice has its business side as well as its scientific and its philanthropic side, and it is the duty of each member of the profession to do what in him lies to maintain its rights and privileges intact.

◆

Yeoman.—We have not seen the "puff" in question. It should be remembered that in these cases the medical man generally suffers from the indiscretion of his friends.

Easy.—Probably the candidate would be accepted.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (14th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (15th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-Wes London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.).

FRIDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.).

SATURDAY (17th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (12th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Meeting. Mr. F. C. Wallis: Resection of Small Intestines in a Child.—Mr. F. Jaffery: Urticaria Pigmentosa (?).—Sir Hugh H. Beevor, Bart.: Pulsus Bisferiens.—Mr. A. J. Barker: Congenital Dislocation of the Hip (with skiagrams).—Dr. W. Ewart: Emphysema treated by continuous Elastic Pressure.—Mr. W. H. Battle: Tumour of Femur.—Dr. W. J. Hadley: Two Rare and Interesting Cases of Rheumatism.—Mr. McAdam Eccles: (1) Interstitial Inguinal Hernia; (2) Cruro-scrotal Inguinal Hernia.—Dr. C. W. Chapman: Cyanosis from Birth, absence of Cardiac Murmur.—Dr. S. Mullick: Displacement of the Heart to the Right Side.—Dr. E. Cautley: The Heart of a Case of Aortic Stenosis exhibited at the previous Clinical Meeting.—Mr. J. L. Thomas: A New Tourniquet. Patients will be in attendance at 8 P.M.

TUESDAY (13th).—CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret-street, W.).—8 P.M. Dr. W. Garnett: Early Stages of Technical Education.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Adjourned Discussion on the following Papers:—On the Conduct of the Mastoid Operation for the Cure of Chronic Purulent Otorrhœa, with special reference to the Immediate Healing of the Cavity in the Bone left by the operation by means of Epithelial Grafts, by C. A. Ballance (with lantern demonstration); with remarks on the Selection of Cases for the Operation, by Sir William Dalby.—The Complete Mastoid Operation for the Cure of Chronic Suppurative Disease of the Middle Ear; observations on the Selection of Cases for Operation, by Mr. A. E. Cumberbatch.

WEDNESDAY (14th).—HUNTERIAN SOCIETY (Theatre of the London Institute, Finsbury-circus).—8.30 P.M. Dr. F. J. Smith: The Influence of Modern Medicine on Surgery (Annual Oration).

THURSDAY (15th).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road).—8.30 P.M. Papers:—Dr. G. F. Blacker: Experiences in Feeding Delicate and Premature Children with Modified Milk.—Mr. F. Jaffrey: Calculous Suppression of Urine treated by Operation.

FRIDAY (16th).—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Paper: Dr. E. W. Hope: Insanitary Property and Workmen's Dwellings in Liverpool.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (12th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Mr. E. T. Collins: The Anatomy and Pathology of the Eye. (Erasmus Wilson Lecture.)

LONDON THROAT HOSPITAL (204, Gt. Portland-street, W.).—4.30 P.M. Dr. Cathcart: Impaired Movements of Vocal Cords. (Post Graduate Course.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. M. Morris: Consultation. (Skin.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—6 P.M. Mr. Beddard: Transfusion and Venesection.

TUESDAY (13th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. C. T. Williams: Consultation. (Medical.)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, W.C.).—3.30 P.M. Dr. Buzzard: Hysteria.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. E. Ray Lankester: The Structure and Classification of Fishes.

WEDNESDAY (14th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Mr. E. T. Collins: The Anatomy and Pathology of the Eye. (Erasmus Wilson Lecture.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—4.30 P.M. Dr. Eddowes: Urticaria. (Post-graduate Course.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. F. Payne: Consultation. (Medical.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Wethered: The Prognosis of Pulmonary Tuberculosis.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Discussion on Insanitary Condition of the London Streets (opened by Mr. W. N. Blair).

THURSDAY (15th).—WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street, W.).—5 P.M. Clinical Demonstration:—Dr. H. Campbell: Cases of Facial and other Cranial Nerve Paralyses.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Lees: Demonstration of Selected Cases.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. Galloway: Dermatological Demonstration. (Post-graduate Course.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—3 P.M. Roentgen Ray Cases:—Dr. H. Low: Demonstration. 4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Beddard: Nature and Treatment of Shock and Collapse.

FRIDAY (16th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Mr. E. T. Collins: The Anatomy and Pathology of the Eye. (Erasmus Wilson Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. D. Grant: Consultation. (Eye, Ear, Nose and Throat.)

During the week marked copies of the following newspapers have been received: *Norfolk Weekly Standard, Rangoon Times, Madras Times, Birmingham Daily Gazette, Liverpool Daily Post, Health, Weekly Budget, Christian World, Sanitary Record, Sheffield Independent, Western Mail, Bradford Observer, Glasgow Herald, Times of India, Pioneer Mail, Citizen, Builder, Scotsman, Architect, Leeds Mercury, Hertfordshire Mercury, Yorkshire Post, Reading Mercury, Brighton Gazette, City Press, [illegible], Bristol Mercury, Local Government Chronicle, Mining Journal, Cork Constitution, Surrey Advertiser, Local Government Journal, National Review, Manchester Guardian, Leicester Daily [illegible], Chorley Standard, Irish Society, Daily Telegraph, Huddersfield Examiner, Carmarthen Reporter, Bakers' Times, Hull Daily News, Eastern Morning News, League Journal, Le Parfait Nourricier (Paris), [illegible] Journal, Preston Herald, Empire, Derby Advertiser, Eastern Post (London), [illegible] Gazette, Public Health, Waterford Chronicle, Munster Express, [illegible], Warwick Advertiser, [illegible] Herald, &c., &c.*

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1899, which was completed with the issue of Dec. 30th, and the Title-page to the Volume were given in THE LANCET of Jan. 6th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1899 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year ...	£1 12 6	One Year ...	£1 14 8
Six Months ...	0 16 3	Six Months ...	0 17 4
Three Months ...	0 8 2	Three Months ...	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Dr. H. E. Annett, Liverpool; Messrs. Armour and Co., Lond.; Accrington Corporation, Medical Officer of Health of; Aston Hall, Sutton Coldfield, Secretary of; Mr. W. R. Alexander, Lond.; Mr. W. H. Austin, Lond.; Alpha, Lond; Advertiser, Marsfield; Mr. W. E. Alderson, Newcastle-on-Tyne; Mr. John Allan, Lond.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Erasmus Wilson Lectures

ON

THE ANATOMY AND PATHOLOGY OF THE EYE

Delivered at the Royal College of Surgeons of England on Feb 12th, 14th, and 16th, 1900

By E TREACHER COLLINS, F R C S Eng ,
ASSISTANT SURGEON TO THE ROYAL LONDON OPHTHALMIC HOSPITAL.

LECTURE I

Delivered on Feb 12th

Mr President and Gentlemen,—There is a law in biology to the effect that the various stages of development through which an individual passes typify to a great extent the history of the race In the course of these lectures I shall have several opportunities of showing that in the study of the embryology of the human eye arrangements of parts are met with differing from what is present in the adult but simulating what is present in lower animals and, further, that when arrests of development occur conditions comparable to what are met with in lower animals, and not in man, sometimes persist

The Eyelids of Animals and the Human Fœtus

As an example I may first draw your attention to the development of the eyelids In a human fœtus of six weeks no eyelids are present, the surface of the eye is directly continuous with the surface of the head In eels and certain other fish there is no covering whatever for the eyes, the skin of the head is uninterruptedly continuous with the anterior layers of the cornea In a human fœtus of about eight weeks the eyelids may be seen just commencing to bud out as little processes of mesoblast covered with epiblast above and below the eye In most of the teleostean fish there is a little fold of projecting skin at the margin of the orbit, which varies in length in different species but does not usually reach the corneal margin In a human fœtus the eyelids having budded out continue to grow over the front of the eyeball until they meet, when the epithelium along the margins becomes connected together, the conjunctiva being formed for a time into a closed sac In the ophidia and some lacertilia the eyelids are permanently united in front of the eye, they are transparent and consist from without inwards of a continuous layer of laminated epithelium fibrous tissue and a single row of epithelial cells The surface of the cornea is covered by but a single row of cells The conjunctiva is a permanently closed sac through which the lacrymal secretion circulates In the human fœtus the eyelids become separated again before birth In many mammals of the feline tribe separation of the eyelids does not occur until some days after birth so that their young are during birth protected from risks of infection of the conjunctival sac by secretion from the maternal passages—a protection which is unfortunately denied to man

Cryptophthalmos

Amongst the congenital malformations met with in connexion with the eyelids there is a condition of which I only know two cases that have been recorded in man but of which I have met with one example in a chick It is termed by Zehender[1] cryptophthalmos In his case there was a total absence of the eyelids and their appendages the eyebrows, the lacrymal glands, and the lacrymal ducts The whole of the front of the eyes was covered by skin, continuous with that of the face and connected with the surface of the eyeball by a subcutaneous cellular membrane The absence of the lids had, as Zehender says, prevented the formation of a conjunctival sac The eyeballs themselves of which Manz made a pathological examination, presented several abnormalities, the chief of these were the imperfect development of the lens and the filling of the anterior chamber with vitreous The optic nerve, retina and its pigment epithelium were quite normal

The second case, which was precisely similar as regards the absence of eyelids and the presence of skin over the front of the eyes, has been described by Van Duyse[2] There was also imperfect development of the parietal bone with meningo encephalocele The hen, the mother of the chick in which I found this condition of cryptophthalmos present, was the daughter of the cock which was the chick s father The same cock had also been the father of a chick with two beaks, of one without any beak, and one with four legs. On removing the feathers from the blind chick I could not find a vestige of the eyelids The skin passed continuously over the orbits and front of the eyes These latter after removal were found to be of normal dimensions Microscopical examination of them shows beneath the laminated epithelium on the surface a dense mass of fibrous tissue, amongst which, near the surface, are collections of round cells and blood vessels, whilst deeper down it is less cellular and vascular, more regularly laminated like the substantia propria of the cornea Attached to the posterior surface of this fibrous tissue and displaced backwards in the eye by it is the iris there being no anterior chamber The iris, the rest of the uveal tract and the retina are very imperfectly developed The pigment epithelium is much broken up and irregularly arranged The lens is small but well formed

It would appear that in these cases the eyelids and the conjunctival sacs having failed to develop and the individuals not living in a fluid medium like fish the epithelium covering the surface of the eyes became desiccated and a tissue similar in character to skin formed in front of them

Congenital Ankyloblepharon

Several cases of congenital ankyloblepharon have been recorded in man, but they are rare The union of the lids may not only be due to a cementing together of the epithelium at the margins but there may be a real membranous union It has most frequently been met with in cases of congenital absence or very extreme mal development of the eyeball Thus out of a series of 30 recorded cases of so-called bilateral congenital anophthalmos which I collected I found that a certain amount of ankyloblepharon was mentioned as being present in nine Middlemore[3] says "I have seen three cases in which the tarsal margins have been coherent from birth The defect has occurred in both eyes; the eyelashes have not been formed and in the situation of the intertarsal slit there has been a narrow sulcus, lined by a delicate vascular portion of skin, which admitted of extension but not of absolute separation In one of the cases the eyeball appeared to be imperfectly developed " Travers[4] mentions a case of co adhesion of the tarsi in a full grown boy whose eye was found perfect after the division though he had been thus blind from his infancy De Haas[5] described an infant in whom the lids were united by several thin tracts of skin attached to the lid margins between the cilia and the mouths of the Meibomian glands When these bands were divided the eyes were found to be normal

Dermoid Growths of the Eye

The cases of cryptophthalmos in which the whole surface of the eyeball is covered with skin though rare, are interesting as offering an explanation of the much commoner malformation in which small patches of skin are found on the surface of the eye Sometimes a portion of the upper eyelid fails to develop, a deep cleft or notch being left in it which is spoken of as a coloboma of the eyelid In many of such cases the surface of the eyeball opposite the gap presents some abnormality In a case recorded by Manz[6] in which the inner portion of the upper lid on each side was absent, bands of skin arose on the surface of each cornea where it was left exposed, and extended upwards in the region of the gaps to the skin of the forehead In a case described by De Wecker[7] there was a small congenital notch in the border of the upper lid and on the surface of the globe was a small nodule of skin which when the eye was closed exactly filled the deficiency left in the lid Little isolated patches of skin spoken of as dermoids are not very uncommonly met with on the surface of the globe apart from any deficiency in the lids They occur most frequently at the sclero-corneal margin opposite the palpebral aperture, more often on the outer than the inner side and a little below the horizontal meridian of the eyeball—that is, in the region of the eye which would remain longest uncovered by the eyelids in their extension over it during fœtal life. Many years ago Ryba[8] suggested—and I think his observations are well borne out by the above cases—that the reason skin formed on the surface of the eye opposite the gap left by a coloboma of the lid was that the lining membrane there not being covered over failed to become mucous membrane, and he further suggested that the dermoid nodules opposite the palpebral fissure probably resulted from an incomplete apposition and union of the margins of the lids, portions of the surface of the eye being left uncovered.

XEROSIS OF THE CORNEA AND CONJUNCTIVA.

The epithelium of the surface of the cornea and conjunctiva differs from that of the skin in the absence of a horny layer; the cells nearest the surface in these parts, unlike those in the superficial layers of the skin, are not shrunken and all possess nuclei. It is the presence of moisture and the constant friction of the lids over the front of the eye in the act of winking which accounts for this difference. That this is so is shown by what happens when their agents are absent. If a staphylomatous cornea protrudes between the lids and is so prominent that a portion of it is not covered by them during sleep, then the surface epithelium on the exposed part is not removed and layers of dry horny cells devoid of nuclei accumulate on the surface. In cases of severe granular ophthalmia or other destructive affections—such as pemphigus, when what is termed symblepharon posterior is formed—much of the retro-tarsal fold of the conjunctiva and its glands are destroyed by cicatricial contraction, and the lacrymal secretion is to a great extent cut off. Then the epithelial cells on the surface of the cornea and conjunctiva, instead of being removed, accumulate and form a dry horny layer on the surface. I have had the opportunity of examining microscopically the whole conjunctival sac and cornea of one such case and the cornea in two others.

Besides the marked thickening of the epithelium and the dryness of its surface layers, I have found in each case numerous down-growing finger-like processes of epithelium, making the base line of the epithelium over the cornea, which is normally straight, very irregular, and so causing its appearance on section still further to resemble that of skin. The down growths have a peculiar and definite arrangement, those in the centre of the cornea passing vertically downwards, those towards the periphery gradually sloping more and more outwards and downwards. These finger-like processes are probably first started by shrinking of the surface due to contraction of the cicatricial tissue in the subjacent structures. To quote another example of the readiness with which the conjunctiva will, under favourable circumstances, take on the characters of skin, I may refer to the operation for ectropion devised by Mr. Tweedy, in which after cutting out a flap of the whole thickness of the lid he utilises a portion of the conjunctival surface to fill up a gap left below the lid after it has been stitched into its required position. The transplanted and exposed piece of conjunctiva is found after a short time to take on all the appearances of skin.

THE INFLUENCE OF FRICTION OF THE LIDS ON THE SURFACE OF THE CORNEA.

The influence which the friction of the lids has in the preservation of the character of the surface epithelium of the cornea is well illustrated by some observations described by George Bull of Paris.[9] He examined the changes produced on the surface of the cornea by a method of entoptic observation in which he allowed the light from a small candle flame five metres distant to be thrown in circles of diffusion upon the retina by a convex lens of about five centimetres' focus, held within two centimetres from the eye. The field seen by this method is circular, more or less uniformly granular, and limited by the dark shadow of the iris. By the passage of the eyelids over the front of the eye Bull has pointed out that two sorts of bright bands bounded by darkened areas may be produced in the field. The first, which he calls temporary, are due to changes in the curvature of the lubricating fluid which the eyelids push before them over the front of the cornea. These temporary bright bands are seen to advance and recede with the movements of the lids, and a single sweep of the lids as in natural winking instantly effaces them. The second sort of bands are termed by Bull persistent; they are produced when stronger and more enduring pressure of the tarsal edge of the lid is made against the cornea and are due to a disturbance of the epithelial surface. These persistent bands are less bright than the temporary ones, indicating that when the disturbance of curvature is in the epithelium it is less in degree than the disturbance of curvature created by a wave of viscous fluid. The act of winking instead of making the persistent bands disappear makes them brighter as they tend to fade. Bull concludes from his observations, all of which I have repeated and am able to confirm, that the tarsal edge of the lid evidently acts as a kind of scraper over the front of the eye. By so doing it must constantly remove any epithelial débris from the surface of the cornea as well as provide fresh supplies of lubricating fluid.

ENTOPTIC EXAMINATION OF THE CORNEA UNDER THE INFLUENCE OF COCAINE AND ERYTHROPHLÆINE.

I have further examined by this entoptic method the condition of the cornea after the application of certain drugs to the eye such as cocaine and erythrophlæine. As is well known, after the application of cocaine to the eye, unless the lids be kept closed the surface of the cornea becomes dry. That this is largely, if not entirely, due to the retraction of the eyelid from stimulation of the unstriated fibres of Müller is well shown by this method of examination. When the eye is well under the influence of the drug the bright temporary bands hardly ever make their appearance in the field, and when they do only at the extreme upper margin. After a while the whole of the field, instead of presenting a comparative uniform granular appearance, becomes irregularly mottled and marked out with a number of very irregular, bright, branching lines like the cracks seen in the glaze of china. Vision with an eye fully under the influence of cocaine, if the eyelids have not been kept closed, is, even for distant objects, somewhat misty, and a dim halo of colours can be seen round bright lights when viewed against a dark background.

The microscopical appearances of the cornea when under the influence of cocaine have been described by Wurdinger[10] who experimented on rabbits, dogs, and guinea-pigs. He found that there was an unevenness of the surface which was due to an irregular diminution of the thickness of the tissues. The anterior layers of the epithelium gradually became thinned and flattened, later the deeper layers began to shrink, and ultimately the external cells were in places cast off at the spots where the epithelium was most damaged. Wurdinger attributed the xerotic condition of the cornea partly to diminished lymph supply from contraction of the blood-vessels, as well as to the dryness produced by exposure. That diminished lymph supply from contraction of blood-vessels alone will not produce the change in the cornea is shown by no alteration occurring after the application of the extract of suprarenal capsule to the eye, which gives rise to a more marked constriction of the conjunctival and scleral blood-vessels than cocaine. In ten normal eyes in which W. H. Bates[11] instilled this drug at short intervals for three hours no desquamation followed. The field examined by the entoptic method after its use shows no alteration whatever from its normal granular appearance.

Erythrophlæine is an alkaloid obtained from an African arrow-poison called "haya." In 1888, when experimenting with a 0 125 per cent. solution of the hydrochlorate to test its reputed local anæsthetic properties, I found that the instillation of a drop into the eye was followed by considerable smarting and irritation, lasting about from 10 to 30 minutes. Slight anæsthesia of the cornea was produced, but hardly any of the conjunctiva, never sufficient to obliterate the smarting caused by a 1 in 40 solution of carbolic acid. After about two hours the sight of the eye in which it had been put became very much blurred, everything appearing as if in a fog, and all lights having a pronounced circle of coloured rings around them, the red rays being the outermost. The position of the red rays was not altered by changes in the refraction of the eye. The nearer the light was to the eye the smaller were the halos, and *vice versâ*. The halos remained stationary whether the light was fixed by the eye or not. The blurring of vision was not due to any alteration in the accommodation of the eye. The cornea on careful examination was found to be slightly steamy. There was no increase in the tension of the globe. The first specimen of erythrophlæine that I used produced slight dilatation of the pupil. A second specimen produced slight contraction. After the use of both of these solutions the coloured halos were seen.

---

[8] Prager Vierteljahrschrift, 1853, Band iii.

[9] Transactions of the Eighth International Congress of Ophthalmology, 1894, p. 107.

[10] Klinisches Monatsblatt für Augenheilkunde, 1886, Band xxiv. S. 140.

[11] Archives of Ophthalmology, vol. xxviii, No. 3, 1899.

Examination of the cornea, when under the influence of the erythrophlæine by the entoptic method above described, shows it to be mapped out with a number of very dark branching lines bounded on each side by light ones, the field retaining its uniform stippled character in the spaces between the lines. These lines commence to appear about three quarters of an hour after the application of a drop but are at first very faint, and do not reach their maximum intensity for two hours—i.e., until the coloured rings are also plainly visible. They last as long as these and are seen for about 12 hours. Slight pressure on the globe so as to increase its tension causes the lines to change so that the part that was dark becomes bright and that which was bright becomes dark. If the pressure is increased they disappear altogether, the field becoming uniformly granular. I find it difficult to conjecture the nature of these lines. The cornea when they are present does not become stained with fluorescine. I made a drawing of them as they appeared in one of my eyes and a few weeks later after a fresh instillation I compared the drawing with their arrangement as then seen. So similar were the number, grouping, and branching of the lines on the two occasions that I cannot help thinking that they represent some definite anatomical structure.

IRIDESCENT VISION.

The halos produced by erythrophlæine cannot be in any way connected with dilatation of the pupil, for they were seen equally well after the use of a specimen which produced slight contraction of the pupil. They cannot in any way be connected with the lens, for they were seen by a patient after a cataract had been extracted to whose eye I applied a drop. They cannot be due to pressure on the retina for there is no increase of tension. The irresistible conclusion is that they are due to the haze of the cornea.

CHANGES IN THE SURFACE OF THE CORNEA IN GLAUCOMA.

In glaucoma, too, when halos are seen, a haze or steaminess of the cornea is present. The changes which give rise to this haze were first pointed out by Fuchs[12] to be due to the collection of minute drops of fluid, which sometimes contain albumin and coagulate in the anterior part of the cornea, between the surface epithelium and the anterior limiting membrane, in the channels in the anterior limiting membrane through which the nerve fibres pass, and in the spaces between the anterior layers of the fibrous tissue forming the substantia propria. In eyes in which increased tension has existed for some time, what appear to the naked eye to be little vesicles may be met with on the surface of the cornea. Microscopically I have found these apparent vesicles to be composed of a loose network of fibres and branching cells with fluid in its mesh situated between the anterior limiting membrane and the epithelium. In some eyes, as these apparent vesicles form, great pain is experienced which is due probably to the stretching of the nerve filaments which pass to the epithelium. This pain lasts until the apparent vesicle collapses, when it is at once relieved. After a condition such as this has existed in an eye for some time a formation of dense fibrous tissue makes its appearance between the epithelium and the anterior limiting membrane, and the anterior limiting membrane in certain positions appears broken in its course by the extension through it from behind forwards of considerable collections of fibrous tissue.

The interpretation of these several changes seems to be that at first, as the result of the increased tension, there is a disturbance in the lymph flow in the cornea, a disturbance which results in œdema and which manifests itself naturally at the part where the pressure is least—namely, towards the anterior surface. The epithelium in places becomes separated from the anterior limiting membrane. The communications between the intercellular clefts within the anterior epithelium and the corneal spaces through the anterior limiting membrane become distended, and some of the spaces between the anterior layers of fibrous tissue are enlarged. At first the distended spaces are filled with the ordinary circulating lymph of the cornea, but if the œdema persists for some time cells find their way into it which proliferate, and a network develops. This loose network and cells later become transformed into dense fibrous tissue resembling that of the substantia propria, but much of it lying anterior to the limiting membrane and in the clefts formed by the immensely distended lymph spaces in it.

TRANSVERSE FILMS OF THE CORNEA.

An avascular development of fibrous tissue between the anterior limiting membrane and the epithelium, together with breaks in its continuity, through which pass bands of fibrous tissue, is met with, not only in eyes which have glaucoma, but also as a localised condition in what is spoken of as transverse films of the cornea. These transverse films are either primary—i.e., occurring in eyes apparently perfectly healthy—or secondary, occurring in eyes otherwise diseased, most frequently in eyes which have for some time been blind. It is probable, however, that both primary and secondary films have the same pathological characters. C. H. Usher, while working with me in the laboratory of the Moorfields Hospital, made a careful examination of the cornea of 13 eyes with secondary transverse films and published a description of them in the hospital's reports.[13] The results of his examinations may be summarised as follows: 1. The antero-posterior diameter of the cornea is increased in the situation of the film and this is usually the thickest part of the cornea. 2. A formation of laminated fibrous tissue is present at the anterior part of the cornea between the epithelium and the normal situation of Bowman's membrane, which in most cases contains a granular material. No blood-vessels are found in this new fibrous tissue. 3. Granular hyaline or entirely granular bands, frequently with a space in front of them, are found at the posterior part of the new tissue, in some cases forming a sharp line between it and the substantia propria. These bands vary much in length, shape, and arrangement. Their breadth varies only to a limited extent, being about equal to that of a normal Bowman's membrane. The number of granules in the bands varies considerably. 4. At parts where the hyaline granular bands exist Bowman's membrane is never found in contact with the epithelium. They may be found directly continuous with Bowman's membrane where it lies in contact with the epithelium. So that there can be no doubt that they are portions of Bowman's membrane which have become granular and divided up. 5 Degenerative changes are found in the epithelium in the situation of the film. 6 A portion of the film treated *en masse* (by cutting a piece off from the anterior part of the cornea), either with strong hydrochloric or acetic acid, showed by the evolution of bubbles that there was calcareous material present in every case in which it was tried.

As I have said in cases of glaucoma of long standing a formation of fibrous tissue similar in appearance to that met with in these films may be found between the epithelium and the anterior limiting membrane which appears to be the result of lymph stasis. The avascular formation of fibrous tissue in these films is probably brought about in the same way, but whilst the changes following glaucoma are comparatively acute the formation of the films is exceedingly slow, often extending over a period of several years. Hence the presence in these latter of calcareous granular-looking incrustations. In glaucoma the formation of vesicles or the later superficial development of fibrous tissue may be met with in all parts of the cornea. In the transverse films the change is confined to the portion of the cornea corresponding to the palpebral aperture and is usually a band situated a little below the middle line. The reason that this area is affected has been usually attributed to its being the part most exposed to irritation from external agents. There is, I would point out, another important cause which appears to have been overlooked and which accounts, moreover, for the way in which these films begin and extend. I refer to the effect of the pressure of the lids on the cornea. A transverse film is never seen to extend quite up to the margin of the cornea, a narrow band of clear tissue being always left between it and the extreme margin. The opacity usually commences to form in two places, on the outer and inner sides of the cornea, and then each patch gradually extends inwards until they meet and one complete horizontal band results. It always, however, remains thickest and densest at its two starting points. In a complete film the lower border is nearly straight whilst the upper is curved, the convexity being downwards.

---

[12] Archiv für Ophthalmologie, 1881, Band xxvii., Abtheilung 3, S 66.

[13] Vol. xiii., 1893, p. 508.

We have seen from the observations of Bull that the pressure of the margin of the lid on the cornea may be such as to cause a lasting depression in the surface epithelium, and it is not difficult to understand that this sort of squeegee action of the lids in their passage over the surface of the cornea would tend to prevent the accumulation of œdematous fluid in spaces beneath the epithelium, unless the obstruction to flow of lymph in the cornea was fairly acute. The part of the cornea least affected by this lid pressure is opposite the palpebral aperture, and as the central portion of it projects most from the surface of the globe it is pressed on more than the sides, so that the peripheral portions of the cornea opposite the palpebral aperture are the least affected by lid pressure and are the parts in which the transverse film commence and are most intense. That a film does not extend quite up to the corneal margin is probably accounted for by that region being directly under the influence of the terminal vascular loops which tend to absorb any œdematous exudation in their immediate vicinity.

VESICLES IN THE CORNEAL EPITHELIUM AND FILAMENTARY PROCESSES.

Besides the vesicle-like formations at the anterior surface of the cornea, which are due to the separation of the epithelium from the anterior limiting membrane, others are met with which make their appearance in the substance of the epithelium itself. I published a drawing and description of these in the Moorfields Hospital Reports[14] for 1890. They are most frequently met with in glaucomatous eyes, but may occur where no increase of tension is present. J. P. Nuel,[15] who has more recently investigated this form of epithelial change, finds it to be due to a hyaline or mucoid degeneration of the cells. He has been able to trace all the stages in the gradual alteration of the cells, showing how they first become enlarged and then distended by the formation of a hyaline or mucoid substance in them, how several contiguous cells are often affected, their cell-walls ultimately becoming so attenuated that they break through into one another, little vesicles resulting. As these vesicles form the cells immediately surrounding them, from the pressure to which they are exposed, become flattened out. The ones in front and behind the vesicle become flattened so that their long axis is horizontal, whilst those at the sides have their long axis vertical. When two vesicles form close together a ridge of cells arranged vertically separates them. When, as ultimately happens, the vesicles open out this ridge of vertically placed cells remains as a filamentary process on the surface of the cornea. The way in which these vesicles tend to produce elevations of vertically placed cells helps us, I think, to understand how the filamentary formations met with in what is termed by Leber "filamentary keratitis" may be started. The filamentary formations in this disease have been shown by Nuel and Hess to be composed of a central core of twisted and much elongated epithelial cells, the long axis of which is for the most part vertical to the surface, and they have further shown that cells removed from the surface of the cornea in the neighbourhood of the filiform processes are frequently undergoing a hyaline change.

THE DEVELOPMENT OF THE CORNEA AND ITS POSTERIOR LIMITING MEMBRANE.

The development of the cornea in the chick has been described as follows:[16] "The substantia propria corneæ first appears in the chick as a thin homogeneous layer lying immediately within this epithelium (the surface epithelium). Into this homogeneous layer mesoblastic cells pass from the margin, greatly thickening it and producing eventually the regular layers of fibrous tissue which are characteristic of the cornea. No cells pass into the most anterior or into the most posterior stratum which remains homogeneous (anterior and posterior homogeneous lamellæ of Bowman). The epithelium of the posterior homogeneous lamella or membrane of Descemet is derived from mesoblast cells, which grow in like the corneal corpuscles from the margin and spread themselves over the posterior surface of the cornea, thus separating this from the iris and anterior surface of the lens." With regard to the origin of the homogeneous layer which first separates the lens vesicle from the surface epithelium in the chick and which remains ultimately as the anterior and posterior elastic laminæ two different views have been put forward. Kessler regards it as a secretion of the epidermis and Kölliker as of mesoblastic origin. In mammals this homogeneous layer has not been met with. Hertwig says[17]: "As soon as the lens vesicle in mammals is fully constricted off it is already enveloped by a thin sheet of mesenchyma with few cells, which separates it from the epidermis. The thin layer is rapidly thickened by the immigration of cells from the vicinity. Then it is separated into two layers, the pupillary membrane and the fundament of the cornea." He makes no mention as to the mode of origin of the anterior and posterior elastic laminæ in mammals.

In fœtal mice which I have examined I find at one stage the surface epithelium separated from the lens by a collection of round cells, but no vestige amongst them whatever of a hyaline membrane. In sections of a human fœtal eye of between the first and second months I find the cornea to consist from before backwards of the following layers. Epithelial cells in places appearing two rows thick; immediately in contact with them, and not separated by any homogeneous membrane, layers of cells with elongated nuclei and fibres. The nuclei of these cells are very much closer together than those of the corneal corpuscles in the adult cornea, the amount of fibrous tissue between them being very much less. Behind this laminated fibrous and cellular tissue is seen an extremely thin hyaline layer, posterior to which are closely packed cells with round nuclei, showing a tendency to arrangement into two layers, the anterior evidently being the lining endothelium of Descemet's membrane and the posterior the commencement of the antero-fibro-vascular sheath of the lens. I am unable to find any blood-vessels amongst the round cells, though there are many already formed at the posterior part of the lens. In a specimen I have of a human fœtal eye of the fourth month blood-vessels are distinctly seen in the antero-fibro-vascular sheath. The posterior elastic lamina is still only seen as an exceedingly delicate line, and nothing of a homogeneous layer is yet visible between the anterior epithelium and the substantia propria of the cornea. In a human fœtal eye, said to be of the sixth month, Bowman's membrane, the anterior elastic lamina, is very distinctly seen, and the posterior elastic lamina is considerably wider than it was at the fourth month.

It is evident, then, from this that in mammals there is a stage in the development of the cornea where no elastic membrane is present. In man, when a very delicate rudiment of the posterior elastic lamina is just discernible, it is already lined by endothelial cells, and from this time onward it gradually increases in thickness. That there are physical and chemical differences between Bowman's and Descemet's membranes has been repeatedly pointed out, the former being similar in character to the substantia propria whilst the latter resembles closely elastic tissues. This difference I have lately further been able to emphasise by treating sections with acid solutions of orcein. After they have been allowed to soak in it for some hours Descemet's membrane can be made to stand out a reddish-brown colour, while the substantia propria and Bowman's membrane stains a dull pink. How then is Descemet's membrane formed? Is it the product of the endothelial cells lining it? In determining this point a study of the pathological changes observed in connexion with it are of considerable assistance. On the inner surface of Descemet's membrane in diseased eyes little hyaline nodules are sometimes seen indistinguishable in structure from the membrane itself. It seems unlikely that an inert basement membrane would give rise to such outgrowth and much more probable that the active endothelial cells lining it should undergo some change which results in their production. The nodules, moreover, are never met with except on the inner surface where the cells are situated. If they were simply thickenings of the membrane itself it seems reasonable to expect that they should sometimes be met with on both surfaces.

PATHOLOGICAL NEW FORMATIONS OF DESCEMET'S MEMBRANE.

Sometimes after perforating wounds of the cornea a new formation of a hyaline membrane may be met with thus.

[17] Text-book of Embryology, translation of the third German edition, p. 477.

B. Gepner, jun., described (in 1890[18]) the case of a man, aged 21 years, who had an iridectomy performed several years previously for iritis. The eye was removed on account of inflammation following a blow. A gap was found in Descemet's membrane in the region of the cicatrix, which was bridged across by a layer of hyaline membrane of the same structure as Descemet's membrane and lined by endothelial cells. Wagenmann (in 1891[19]) recorded the case of a patient, aged 57 years, who two and a half years previously had had a cataract extracted from his eye by the modified linear operation of von Graefe, and who while in the hospital for operation on his other eye died from pneumonia. The eye first operated on was removed shortly after death, and on microscopical examination of the seat of the wound the two cut extremities of Descemet's membrane could be seen, separated by a slightly protuberant film of tissue, posterior to which was a layer of newly formed hyaline substance lined by endothelial cells. Wagenmann has no doubt that the hyaline layer was derived from the endothelium. Alt mentions a case[20] in which there was a considerable new formation of fibrous tissue on the inner surface of Descemet's membrane, which was covered on the surface towards the anterior chamber by a newly formed secondary membrane of Descemet lined by endothelium, and he says: "I think that this case shows that Descemet's endothelium cannot only form lamellated connective tissue, similar to that of the corneal tissue, but that it can form, and, perhaps, originally forms, the vitreous membrane, which we call that of Descemet."

I have myself recorded two cases with a similar new formation and I have met with a third. My first case was that of a man, aged 46 years, who 26 years previously to excision had received an injury to his eye from a piece of steel. There was a faint scar at the lower part of the cornea and in the eye a small fragment of metal two millimetres square. Microscopical examination of sections of the cornea in the line of the scar showed on the posterior surface the two divided ends of Descemet's membrane turned forwards and separated from one another by fibrous tissue, whilst a thin hyaline layer bridged over the gap posteriorly. This hyaline layer could be traced for a short distance in contact with, but distinct from, Descemet's membrane with which a little further on still it became blended. Endothelium continuous with that on Descemet's membrane lined its posterior surface.

The second case was that of a man, aged 44 years, who three years previously to excision had had an iridectomy performed for glaucoma. The divided ends of Descemet's membrane in the region of the scar were found to be widely separated; the more peripheral end was curved a little backwards. Between the two ends there projected backwards some new-formed fibrous tissue, which at one part was dense and laminated, resembling closely normal corneal tissue. Some of this new-formed fibrous tissue extended a short distance inwards towards the centre of the cornea behind Descemet's membrane. On the posterior surface of this dense new-formed laminated fibrous tissue was seen a thin hyaline membrane of the same structure as the posterior elastic lamina to which on the inner side it became united at an acute angle. It was lined by endothelium continuous with that on the posterior surface of the cornea elsewhere.

The third case was that of a girl, aged 16 years, the subject of congenital syphilis, who had had interstitial keratitis and in whom the eye had been operated on two and a half years previously to its enucleation. Two scars were found in the cornea; part of the iris and the lens had been removed. Extending backwards from each scar in the cornea to the lens capsule was a mass of fibrous tissue. At either side of each of these bundles of fibrous tissue the hyaline layer of Descemet's membrane seemed to divide into two. The anterior parts, of the same thickness as the membrane elsewhere, were continued on for a short distance lying embedded in the fibrous tissue and then terminated abruptly; they had no endothelial cells lining them. The posterior divisions which were thinner than the anterior, but lined by endothelial cells continuous with the endothelial cells of Descemet's membrane elsewhere, and ran for some distance along the margins of the bands of fibrous tissue connecting the lens capsule with the back of the cornea.

If, then, as seems to be shown by the above cases, under some abnormal stimulus the endothelial cells lining the posterior limiting membrane are capable of producing nodules or a layer of a substance indistinguishable in structure from that membrane, it seems fair to assume that it itself is originally developed from them.

FORMATION OF HYALINE MEMBRANES ON THE ANTERIOR SURFACE OF THE IRIS.

The anterior surface of the iris, like the posterior surface of the cornea, is covered by a single layer of flattened endothelial cells, but beneath the endothelial cells of the iris there is not, as beneath the endothelial cells of the cornea, a hyaline membrane. It is interesting, however, to note that under certain abnormal conditions a hyaline membrane like that of Descemet's may be developed immediately underneath the cells on the surface of the iris. I have met with it as what was probably a congenital abnormality, and also as the result of a pathological change late in life. The eye in which this change was probably congenital was a buphthalmic one, which was removed from a girl, aged seven years. It had been noted as larger than its fellow since birth and there had never been any inflammation in it. There was an adhesion of the iris to the back of the cornea a little above its centre; where it was attached Descemet's membrane was thickened. The endothelium lining the latter turned round the edge of the synechia and was continuous with that on the surface of the iris, which was unusually well defined. On one side of the synechia starting from the thickened part of Descemet's membrane and extending for some distance beneath the endothelium on the anterior surface of the iris was a thin hyaline layer.

The eye, in which the formation of a hyaline membrane in the iris probably occurred late in life, was removed from a woman, aged 67 years, who had had absolute glaucoma of some years' duration. The angle of the anterior chamber was closed by adhesion of the root of the iris to the periphery of the cornea. The chamber itself was filled by a loose network of fibrous tissue in which blood-vessels had developed, and in the meshes of which were numerous cells of an endothelial type, probably derived from those on the back of the cornea, and cholesterine crystals. The whole of the surface of the iris was covered by a hyaline membrane, thicker in some parts than in others.

LECTURE II.

Delivered on Feb. 14th.

RELATIVE SIZE OF THE CORNEA TO THE EYEBALL IN MAN COMPARED WITH OTHER MAMMALS.

MR. PRESIDENT AND GENTLEMEN,—The cornea in man's eye is smaller relatively to the size of the globe than in any other mammal. In all mammals below man the diameter of the cornea measures more than half the antero-posterior diameter of the globe. In the chimpanzee it is about half. In man alone is it considerably less than half. The following table (Table I.) shows the dimensions of the eyeballs and corneæ of a series of different mammals which I have had the opportunity of measuring:—

TABLE I.

—	Diameters of the eyeball		Diameters of the cornea.	
	Antero-posterior	Lateral.	Lateral.	Vertical.
Man	24·8 mm	24·4 mm	11·6 mm	11·0 mm.
Chimpanzee ...	19·0 ,,	18·0 ,,	10·5 ,,	—
Rhesus monkey (India)	19·5 ,,	19·0 ,,	12·0 ,,	11·0 mm.
Capuchin monkey (South America)	18·5 ,,	19·0 ,,	11·0 ,,	10·5 ,,
Rabbit	16·0 ,,	20·0 ,,	15·0 ,,	—
Mouse	4·0 ,,	5·0 ,,	3·0 ,,	—
Civet cat	11·0 ,,	17·0 ,,	13·0 ,,	—
Cat	22·0 ,,	21·0 ,,	18·0 ,,	—
Horse	45·0 ,,	51·0 ,,	26·0 ,,	—
Sheep	27·0 ,,	23·0 ,,	19·0 ,,	15·5 mm
Ox	36·0 ,,	33·0 ,,	27·0 ,,	22·0 ,,
Pig	23·5 ,,	24·0 ,,	17·0 ,,	14·0 ,,
Wallaby	18·0 ,,	19·0 ,,	14·0 ,,	—

[20] American Journal of Ophthalmology, vol. xiii.

[It is this alteration in the relative size of the cornea to the eyeball in man which gives to him the characteristic feature of having a portion of the sclerotic and conjunctiva exposed to view in the palpebral aperture, and which renders him liable to two affections of the conjunctiva not met with in animals—namely, pinguecula and pterygium.

Relative Size of the Cornea to the Eyeball in Fœtal Eyes of Different Ages compared with the Adult Eye.

In the human eye during fœtal life the relation of the size of the cornea to the globe resembles what is met with in other mammals in the adult state. That is to say, the lateral diameter of the cornea is always more than half the antero-posterior diameter of the eyeball. This is shown in Table II., which gives the measurements of the eyeballs and corneæ from a series of human fœtuses of different ages.

Table II.

Age	No. of eyes examined.	Measurements of the eyeball in millimetres.			Measurements of the cornea in millimetres.	
		Antero-posterior	Vertical.	Lateral	Vertical	Lateral
Fourth month	2	8·5	8·0	8·0	4·5	5·0
Sixth month	2	10·3	9·75	10·0	5·5	6·0
Seventh to eighth month	8	14·3	12·6	13·2	7·5	8·0
Ninth month ..	1	17·0	15·5	16·0	10·0	10·5
Adult		24·8	24·0	24·4	11·0	11·6

Diminution of the size of the cornea in relation to the size of the eyeball lessens the space occupied by the filtration area relatively to the amount of contents in the globe.

The Relation of Parts about the Angle of the Anterior Chamber in Man and Other Mammals.

I shall now proceed to show that this lessening of the space occupied by the filtration area in man's eye, as compared with other mammals, is accompanied by considerable alteration in arrangement of parts about the angle of the anterior chamber. In man the ligamentum pectinatum begins by the splitting up of the hyaline layer of Descemet's membrane into a number of trabeculæ, which, lined by endothelial cells, are prolonged outwards. Some of the innermost of these turn round the angle of the chamber and pass to the root of the iris; others give origin to the ciliary muscle and the outermost are inserted into the sclerotic. The structure in antero-posterior sections has a laminated appearance and between the trabeculæ are narrow slit-like spaces. The distance between the point where Descemet's membrane begins to split up into the ligamentum pectinatum and the extreme angle of the anterior chamber measures on an average 0·8 of a millimetre. The canal of Schlemm overlies the ligamentum pectinatum and the extreme outer part of the angle of the chamber, so that if a line vertical to the surface of the eye were drawn backwards through the centre of the canal of Schlemm it would pass into the angle of the anterior chamber. If the same line were continued backwards it would almost pass through the large circular artery at the base of the iris and only a small portion of the ciliary processes would lie to its inner side.

The ligamentum pectinatum reaches its greatest development in the ungulata. Amongst them I have examined sections from the eyes of horses, sheep, oxen, and pigs. In these it is composed of an external laminated part with slit-like spaces having much the same arrangement as the ligament in man, and an inner part consisting of an irregular network of trabeculæ with large cavernous spaces between them, whilst in some sections on the side bounding the anterior chamber a prolongation of fibrous tissue, like that on the anterior surface of the iris, passes forwards to be attached to the back of the cornea. It is these fibrous tissue prolongations occurring at regular intervals which give the ligament its notched appearance. The angle of the anterior chamber in these animals does not extend outwards beyond the point where Descemet's membrane begins to split up, so that a line drawn backwards vertically to the surface of the eye through the centre of Schlemm's canal will not pass through the angle of the anterior chamber, but will be some distance outside of it, and the large circular artery of the iris together with a large portion of the ciliary processes will be to its inner side. In the kangaroo the arrangement is very similar to that in the ungulata, the cavernous part of the ligamentum pectinatum, however, not being quite so extensive.

In the carnivora, amongst which I have examined the eyes of dogs, cats, and foxes, the trabeculæ of the ligamentum pectinatum are very delicate, the laminated portion small, but the cavernous portion very extensive, extending backwards a considerable distance beyond the termination of Descemet's membrane and having very large spaces in it. The angle of the chamber, as in the ungulata, ends where Descemet's membrane begins to split up, and the line drawn back through the canal of Schlemm would be some distance outside of it and have the circular artery of the iris and a large part of the ciliary processes to its inner side. The same applies to the eyes of rodents, in whom the laminated portion of the ligament is still less marked than in the carnivora, while the space between the trabeculæ of the cavernous portion are very large.

Among the quadrumana I have examined sections of the eyes of a South American monkey (capuchin) and Indian monkeys (rhesus) and a chimpanzee. In them the arrangement of parts about the angle of the anterior chamber has a much closer resemblance to that met with in human eyes than that in other mammals. There are, however, slight differences to be observed. In them, and especially in the chimpanzee, the innermost trabeculæ of the ligamentum pectinatum are more widely separated, bend down sooner to be attached to the root of the iris, and have larger spaces between them than in the human eye. They form a modified cavernous zone.

No prolongation forwards of fibrous tissue from the anterior surface of the iris to the back of the cornea on the anterior chamber side of the ligamentum pectinatum is met with in them as in other mammals. The angle of the anterior chamber is not so rounded as in man. A line drawn vertically backwards through the canal of Schlemm would, as in man, pass into the extreme angle of the anterior chamber and leave the greater part of the ciliary processes external to it.

Development of the Ligamentum Pectinatum in the Human Eye.

The fibres of the ligamentum pectinatum when treated with reagents and stains behave in precisely the same way as the hyaline layer of Descemet's membrane. In sections stained with acid orcein I have found them picked out a reddish-brown colour like Descemet's membrane. As I have shown, there is considerable evidence to prove that Descemet's membrane is the product of the endothelial cells lining it. It would seem probable, therefore, that the fibres of the ligamentum pectinatum are the products of the endothelial cells lining the spaces of Fontana. In sections of a human fœtal eye in which the iris is just beginning to bud out from the ciliary body and to insinuate itself between the cornea and lens I find that the site of the ligamentum pectinatum is occupied by a collection of round cells radiating from the single row lining the back of the cornea and blending, without any line of demarcation, with others which form the basis of the ciliary muscle. Schlemm's canal can be distinguished as a ring of cells. In a human fœtal eye of about the fourth month the ligamentum pectinatum and ciliary muscle are distinctly differentiated; the former consists of very delicate fibres with cells lining them and spaces between. Though the parts are small there is a portion of the ligamentum pectinatum comparable to what I have described as the cavernous zone in lower mammals. The angle does not extend outwards beyond the termination of Descemet's membrane, and a vertical line drawn backwards through the canal of Schlemm is external to the angle of the anterior chamber, while the large circular artery of the iris and the ciliary processes are internal to it. In a fœtal eye of the seventh month the trabeculæ of the cavernous zone are more spaced out, but a line drawn vertically backwards through Schlemm's canal still passes externally to the angle of the anterior chamber. In the sections of a human fœtal eye at birth I have found delicate trabeculæ of fibres stretching across what would have ultimately become the angle of the anterior chamber, much in the same way as I have found fibres of the ligamentum pectinatum bend down to the root of the iris in the eye of the chimpanzee.

It will be seen, then, that the diminution in the relative size of the cornea to the globe in man's eye, as compared with other mammals, is accompanied by a simplification of the structure of the ligamentum pectinatum and a prolongation of the anterior chamber outwards Further, in the process of development the human eye passes through stages in which the relative size of the cornea to the globe and the relation of parts about the angle of the anterior chamber resemble that met with in animals.

CONGENITAL ABNORMALITIES OF THE LIGAMENTUM PECTINATUM AND THEIR RELATION TO CONGENITAL GLAUCOMA.

The congenital abnormalities which are met with in connexion with the ligamentum pectinatum are of special interest in the connexion which they have with some forms of buphthalmos. It must be borne in mind that the condition of buphthalmos is simply a manifestation of increased tension in a child's eye, and that as there are many causes which may give rise to increase of tension, so buphthalmos may be brought about in a variety of ways. As can be easily understood, congenital defects in the network of fibres at the angle of the anterior chamber, through which the aqueous humour filters out of the eye, would be exceedingly liable to cause some obstruction to its exit resulting in increase of tension. In a congenitally buphthalmic eye, removed from a boy, aged 14 years, I have found the ligamentum pectinatum to be completely absent. The posterior limiting membrane, instead of splitting up into a number of fibres at the angle of the anterior chamber, continued round it and extended for a short distance along the anterior surface of the iris as a hyaline structure lined by endothelial cells which terminated rather abruptly. Externally to the angle of the chamber in this eye there was a broad adhesion of the root of the iris to the sclerotic, to which also the ciliary muscle was attached, but neither fibres of the ligamentum pectinatum nor a canal of Schlemm could be detected.

Out of six congenitally microphthalmic human eyes which I have measured (Table III.) I have found four in which the lateral diameter of the cornea was more than half the antero-posterior diameter of the globe, one in which it was exactly half, and one in which it was slightly less than half. So that in all except one of these eyes the relation of the size of the cornea to the globe resembled the pre natal or pre-human condition.

TABLE III.

No.	Eyeball.			Cornea.	
	Antero-posterior.	Lateral	Vertical	Lateral.	Vertical.
1	19·0 mm.	18·0 mm.	18·0 mm.	9·5 mm.	8·5 mm.
2	17·0 „	18·0 „	16·5 „	8·25 „	7·5 „
3	15·5 „	—	14·0 „	9·0 „	—
4	13·5 „	12·0 mm	12·0 „	8·5 „	5·5 mm.
5	19·0 „	20·0 „	20·0 „	11·5 „	10·5 „
6	20·0 „	20·0 „	20·0 „	11·0 „	10·5 „

No. 2 in the above table was an eye which had coloboma of the iris, displacement of the lens backwards, and other congenital defects (a full description of it is published in the Transactions of the Ophthalmological Society of the United Kingdom, vol. xiii, p. 116). In sections of it the extreme angle of the anterior chamber is seen to be almost on a level with the termination of Descemet's membrane. Directly this membrane has split up into the ligamentum pectinatum some of the fibres of the latter curve back almost at a right angle and pass to the root of the iris. Between the trabeculæ of the ligamentum pectinatum nearest the angle of the anterior chamber the spaces are large. A line drawn vertically backwards through the canal of Schlemm passes through the ligamentum pectinatum, not through the angle of the anterior chamber. The position of the ciliary processes is much distorted owing to the faulty position of the lens.

No. 3 in the table was an eye with a congenitally persistent and patent hyaloid artery and fibrous tissue formation in the vitreous chamber (a detailed description of it is given in the Royal London *Ophthalmic* Hospital Reports, vol. xiii., p. 92). In sections of it the canal of Schlemm is seen some distance externally to the angle of the anterior chamber. The ciliary processes and large circular artery of the iris are well external to a line drawn vertically backwards through it. There is a well-marked cavernous zone to the ligamentum pectinatum.

No 4 in the table was a microphthalmic eye, a description of which I will give later. In it the condition of the ligamentum pectinatum and the relation of parts about the angle of the anterior chamber are seen to be similar to that in No. 3

No. 5 in the table had considerable defect in the development of the iris in its whole circumference, which led to its being described clinically as a case of irideræmia (a detailed description of it is published in the Transactions of the Ophthalmological Society, vol xiii., p. 128). The condition of the ligamentum pectinatum in this case closely resembles that met with in the ungulata. In some sections portions of the fibrous tissue from the anterior part of the iris seem to pass forwards to the posterior surface of the cornea in the position where Descemet's membrane ends and the ligamentum pectinatum begins. Externally to this prolongation forwards of iris tissue are some irregular trabeculæ with large spaces between them, and anteriorly and externally to this cavernous zone are the laminated fibres of the ligamentum pectinatum with slit-like spaces between them.

In these eyes the structure of the ligamentum pectinatum and the relation of parts about the angle of the anterior chamber seem to have remained in their fœtal condition and to have simulated that met with in lower mammals. Probably on account of the smallness of the eyeballs these abnormalities in the filtration area did not cause sufficient obstruction to the exit of the aqueous humour to give rise to increase of tension. In several congenitally buphthalmic eyes bands of adhesion have been seen stretching across the angle of the anterior chamber between the root of the iris and the periphery of the cornea. These sometimes consist of delicate fibres only and are sometimes quite broad adhesions. As the eyeball enlarges and the anterior chamber becomes deepened these adhesions may break through, then loose tags of fibres are met with. Mr. Richardson Cross[21] published the description of a careful microscopical examination which he had made of three congenitally glaucomatous eyes Speaking of the filtration area in these eyes he says: "There was in No. 1 a definite adhesion of the root of the iris to the ligamentum; No. 2, no definite adhesion, but strands of tissue suggestive of a former contact of iris and cornea which has given way; No. 3, distinct block of considerable width occluding the angle" I have elsewhere described these adhesions as due to a congenital failure in the complete separation of the anterior surface of the iris from the posterior surface of the cornea. This they certainly are, but the more extended examination which I have recently made of the eyes of animals leads me to think that some of them are better spoken of as an abnormal persistence of the pre-human or pre natal condition of the ligamentum pectinatum.

ARRANGEMENT OF PARTS ABOUT THE ANGLE OF THE ANTERIOR CHAMBER IN BIRDS, REPTILES, AND FISH.

Before passing from the consideration of the arrangement of parts about the angle of the anterior chamber I wish to refer briefly to the examinations of this region of the eye which I have made in animals other than mammals. In birds, in whom the cornea is very convex, the front portion much prolonged forwards, and the anterior chamber very deep, the ligamentum pectinatum is an extensive structure. Thus in a pigeon's eye I find it to consist of a number of radiating delicate fibres and branching cells. Starting at the sclero corneal margin a little anterior to the level of the root of the iris it extends backwards a considerable distance between the striated muscle of Crampton and the portion of the ciliary body connected with the ciliary processes. The canal of Schlemm is large and in the sections remains widely open. In a snake's (coluber natrix) eye the ligamentum pectinatum is seen as a definite collection of fibres stretching from the back of the cornea to the rudimentary ciliary body and the canal of Schlemm is a channel of considerable size. In fish, in which the anterior portion of the eye is much flattened and the anterior chamber very shallow, the arrangement of parts about its angle is of a much simpler character, though they vary considerably in different species. Thus in a carp (carassius auratus) I find at the angle of the anterior chamber, filling a considerable part of the space between the iris and posterior surface of the cornea, a mass of large endothelial cells. No canal of Schlemm is present, but at one part of the circumference of the chamber large blood channels on the surface of the choroid extend forwards between this mass of cells and the iris, and their lumen is only separated from the chamber by a thin vessel wall. In the other teleostean fish which I have examined this mass of cells at the angle of the chamber is much less extensive, the cells themselves being elongated, sometimes branching and forming a network. In none have I met with any regular canal of Schlemm, only the prolongation forwards of a choroidal vessel as above described. In the elasmobranch fish the cells at the angle of the chamber branch more and form a more pronounced network. In the lesser spotted dog fish (scyllium catulus) in the portion of the chamber in the neighbourhood of the campanula and of the ocular cleft, there are some fibres lined by cells which present an arrangement much like the ligamentum pectinatum in mammals, and external to it is a large channel which can be traced back to communicate with the choroidal and anterior perforating vessels.

[21] Transactions of the Ophthalmological Society of the United Kingdom, vol xvi.

The Ciliary Body the only Source of Intra-ocular Nutrient Fluid in Mammals.

In man and other mammals anatomical, clinical, and experimental evidence goes to show that the fluid which circulates in the vitreous and aqueous chambers, and which gives nutriment to the lens, is secreted by the ciliary body. In them it would seem that this is its only source and that the other vascular structures in the eye play no part in its production, for we find that each of them may be absent without any diminution of the intra-ocular tension taking place. In cases where the iris is absent congenitally or as the result of traumatism normal tension is as a rule fully maintained. So also is it when the retinal circulation is completely blocked by embolism of the central artery, or when there is almost complete congenital absence of the choroid, as in a remarkable case shown at the Ophthalmological Society by J. Tatham Thompson last year.[22] In it ophthalmoscopically the fundi presented throughout the appearance of dazzling white sclera, with retinal vessels coursing over it as seen in coloboma of the choroid, no chorio-capillaris or red reflex being seen except at the macular region. The following is a case in which as the result of the operation of optico-ciliary neurectomy, performed for the relief of pain in glaucoma, the retina and choroid became completely atrophied and yet the tension remained increased.

The patient was a man, aged 44 years, who had had an iridectomy performed on the eye for acute glaucoma which did not, however, relieve the tension. The eye became blind and the pain continued but he refused to have it removed, so five months after the iridectomy an optico ciliary neurectomy was performed. The pain was then for a time relieved, but two years later it had again become so severe that he consented to have the eye excised. The tension at that time was noted as + 3 On pathological examination of the eyeball the lens, which was clear, appeared to be healthy. The vitreous was only slightly shrunken. The choroid and retina, as far forwards as the equator of the globe, were most extremely atrophied. Microscopically no blood-vessels could be detected in the former, its elastic lamina being the only part of it that could be made out, while the latter was represented by a strand of fibrous tissue with a few scattered pigment epithelial cells in it. In front of the equator the atrophy of these structures was less marked; a few blood-vessels were present in the choroid, while in the retina the two nuclear layers could be differentiated though just behind the ora serrata it had some cystic spaces in it. The ciliary body was not more atrophied than was to be expected in a case of glaucoma of such long standing.

Comparative Anatomy of the Ciliary Body.

In other animals than mammals and in the human fœtal eye there are other, sources for nutrient supply to the intra-ocular structures in place of, or in addition to, the ciliary body. In eels both the common and conger (anguilla anguilla and conger vulgaris) and in a species of carp (carassius auratus) I find there is no ciliary body, no pars ciliaris retinæ. The retina proper ends at the base of the iris and is then continued, on the back of that membrane, as a single row of cells which are at first unpigmented and only become pigmented a short distance from where they turn round at the tip to join the outer deeply pigmented layer of the secondary optic vesicle. In the other teleostean fish, of which I have examined sections—viz , whiting (gadus merlangus), cod (gadus morrhua), mackerel (scomber scombrus), and plaice (pleuronectis platessa)—the termination of the retina does not extend quite so far forwards, it does not quite reach up to the root of the iris, and whereas in the former it extends as far as, or farther than, the anterior margin of the cartilage in the sclerotic, in these latter it is situated behind that point. The pars iridis retinæ has, however, the same arrangement. Amongst the elasmobranch fish I have sections from the thornback (raja clavata), the lesser spotted dog-fish (scyllium catulus) and the spring dog-fish (acanthus vulgarus). In them I find the displacement backwards of the anterior termination of the retina still more marked. The area which exists between it and the root of the iris is thrown into shallow folds laterally and has some slight elevations and depressions antero-posteriorly. The inner row of cells which line this area, which may be regarded as the pars ciliaris retinæ, are unpigmented, whilst both layers of the secondary optic vesicle on the back of the iris are pigmented. Immediately outside the pigmented layer of the rudimentary ciliary body large blood-vessels are seen. In sections of the spring dog-fish passing across the campanula elevations and depressions much more pronounced and closely resembling the ciliary processes in a mammal's eye are met with.

I have sections of the eyes of the following reptiles: the land tortoise (testudo Græca), the slow worm (anguis fragilis), the sand lizard (lacerta agilis), and the common ringed snake (coluber, natrix). In all except the last the ciliary body is represented by a short area, without any elevations or depressions, situated between the termination of the retina and the root of the iris, which is lined by a single row of unpigmented cells inside the pigment epithelial layer. In the snake there is a well-marked fold protruding inwards in the ciliary region lined by columnar-shaped unpigmented cells.

The source of the intra-ocular nutrient fluid in animals, in which there is no ciliary body or in which it is only very rudimentary, can only definitely be determined by experiment. The following anatomical points are, however, very significant. In fish the anterior chamber is comparatively very shallow and the amount of aqueous humour very small. In all those of which I have examined sections the blood-vessels in the iris situated immediately external to the pigment epithelium are large and numerous. In eels I find blood-vessels attached to and forming a network in the hyaloid membrane of the vitreous humour. The main trunk from which these vessels are derived passes in from the choroid along the lower border of the optic nerve through a cleft in the two layers of the retina. In the other teleostean fish which I have examined the line of the ocular cleft in the retina is discernible in its whole length. Blood-vessels pass through it, forming a vascular process which projects slightly into the vitreous chamber. These vessels start from a rete mirabile which is met with in the choroid of these fish surrounding the optic nerve, and which has been termed the choroidal gland. In the elasmobranch fish in which ciliary processes are met with there is no rete mirabile in the choroid and no persistent cleft with a projecting vascular process.

In many reptiles a collection of blood-vessels termed the falciform process protrudes into the vitreous chamber which in birds is modified into the pigmented plicated structure called the pecten. I have bleached sections of the pecten from a cock's eye. I find it composed of some large main blood-vessels and many very small ones the latter having entirely cellular walls. In fact, it closely resembles in structure the choroidal coat of which it is a prolongation, having, however, a rather finer capillary plexus. Birds, therefore, not only possess well-formed ciliary processes but also a special vascular arrangement in the vitreous chamber. In neither of the two lowest and very exceptional mammals the ornithorrhynchus and the echidna is any trace of a pecten to be found. The ciliary processes in these animals, though not so markedly convoluted as in other mammals, show in antero-posterior sections many well-developed folds. The length and amount of plication of the ciliary processes vary considerably in different mammals, but in all except the quadrumina the extent of the non-plicated area of the ciliary body is markedly less than in man.

[22] Transactions of the Ophthalmological Society of the United Kingdom, vol. xix., p. 140.

Development of the Ciliary Body in the Human Eye.

In a human fœtal eye of the sixth week no iris or ciliary processes can be detected. The cells composing the outer layer of the secondary optic vesicle are not pigmented and the inner layer, which is composed of undifferentiated round cells with large nuclei, is as thick at its anterior termination near the sclero-corneal margin as elsewhere. Even at this early age a blood channel is to be detected passing through the cleft in the secondary optic vesicle into the rudimentary vitreous humour. At the tenth week the anterior termination of the secondary optic vesicle, which lies for some distance in close contact with the sides of the lens, has begun to insinuate itself between the lens and cornea to form the posterior layers of the iris. It has also a little further back, where it lies in contact with the sides of the lens, become slightly corrugated, forming the commencement of the ciliary processes. Its outer layer is by this time deeply pigmented and its inner layer, from the point where it first touches the lens forwards is much thinner than elsewhere, though it apparently consists of more than one row of cells. It remains unpigmented until just before it begins to turn round to join the outer layer. The blood-vessels in the posterior part of the fibro-vascular sheath of the lens are by the tenth week well developed, but I am unable in my sections to detect any in the anterior part of the sheath By the fourth month the ciliary processes have considerably grown; their apices still touch the sides of the lens. The inner layer of the secondary optic vesicle covering them, as in the adult, consists of a single row of unpigmented cells, while on the inner surface of the iris they are pigmented, not, however, so deeply pigmented as they become later. The ora serrata of the retina is situated where the ciliary processes end posteriorly, there being no non-plicated area to the ciliary body. The non-plicated portion of the ciliary body commences to form after the fourth month, gradually lengthening, and the ora serrata gradually being displaced further and further back until the eyeball reaches its full dimensions. The plexus of blood-vessels around the lens I have found still patent in sections of the fœtus at the sixth month: by the seventh month they have quite disappeared. In many congenital microphthalmic eyes which I have examined the non-plicated portion of the ciliary body is seen to be relatively smaller than the rest of the structure

Microphthalmic Eye with Persistent Fœtal Vascular System and Absence of Ciliary Processes.

I have only met with one human eye in which there was anything approaching complete absence of the ciliary processes, and in it the vascular system of the vitreous and lens which exists during fœtal life had failed to become obliterated, its vessels remaining patent and carrying blood. It was a congenitally microphthalmic eye removed from a child two months old by Dr Hector Mackenzie of Torquay, to whom I am indebted for the specimen. It measured only 12 millimetres antero-posteriorly and 11 5 millimetres vertically and transversely. The cornea was clear but small, measuring six millimetres transversely. No iris could be seen through it. The lens appeared opaque and calcareous Microscopical examination of sections of the eye show an exceedingly small rudimentary iris, better formed on one side than on the other. Where best developed it does not measure more than one millimetre in length but possesses a sphincter muscle On the opposite side no sphincter muscle is to be seen; the pigmented epithelium turns forward at the tip to form a nodulated mass. Extending from the anterior surface of the rudimentary iris on one side across the pupil in contact with the anterior surface of the lens to the anterior surface of the iris on the other side is a thin membrane composed mainly of flattened cells with large nuclei. Extending also from the anterior surface of the iris round its pupillary margin and backwards to the sides of the lens is a membrane composed in part of the same flattened cells but having in it besides a plexus of blood vessels. These vessels in the sections are seen to be patent and to contain blood corpuscles; they can be traced forwards to the stroma of the iris, where they join the blood-vessels in that structure Continued backwards they are seen to start from the posterior pole of the lens, where an artery, passing through the centre of the vitreous, breaks up in a thin membrane into numerous branches. The lens is very small and presents a very irregular outline; its nucleus is the only part in which the lens fibres appear well formed; in the cortical portions there is much irregularly arranged hyaline substance. Cells line the whole of the posterior as well as the anterior part of the capsule. At the anterior pole the capsule is much corrugated and on its inner surface is some dense laminated tissue with flattened cells between the laminæ and calcareous deposit, like what is usually met with in anterior polar cataracts. A ciliary muscle is present composed entirely of longitudinally arranged spindle-shaped cells. Its inner surface forms an even curve lined by pigment epithelial cells. On either side of the sections only one small knob-like projection is seen to protrude inwards from it.

The unpigmented layer of cells forming the pars ciliaris retinæ, together with some pigmented cells and the anterior extremity of the retina in the region of the ora serrata, are seen to be in great part in contact with the fibro-vascular sheath surrounding the lens. The sides of the lens, owing to its small size, are separated some distance from the ciliary body. Nowhere is the unpigmented layer of the pars ciliaris retinæ seen in contact with the pigmented layer. The retina at the ora serrata is also separated from the choroid; it is well formed but has several rucks in it radiating from the optic disc. The choroid shows no abnormality. The central artery of the vitreous starts from that in the optic nerve; it is for a short distance surrounded by a sheath composed of long spindle-shaped cells, but anteriorly lies without any sheath in a canal separated only by a hyaline membrane from the vitreous. The detached folds of the pars ciliaris retinæ and the retina itself at the ora serrata where they lie in contact with the fibro-vascular sheath of the lens have cellular connexions with it, while in places very much elongated cells can be seen, apparently partly developed fibres of the suspensory ligament.

The probable explanation of the appearances of the ciliary body in this eye is that at the stage of fœtal life when the portion of the secondary optic vesicle which comes to line the ciliary body lay in contact with the sides of the lens adhesion formed between them which should later have developed into fibres of the suspensory ligament. Owing, however, to the persistence of the blood-vessels in the sheath these adhesions became of a tougher character than usual; consequently when the ciliary body in the process of growth became separated from the sides of the lens, instead of these adhesions stretching out into fibres, a part of the inner layer of the secondary optic vesicle became torn from the outer layer and remained in contact with the lens.

I have previously had the opportunity of examining and recording the appearances of several eyes in which the central artery of the vitreous had remained persistent and patent, but in none of these have I been able to trace the branches into which it broke up round the sides of the lens to join the vessels of the iris, as in this case In the specimens which I have previously examined, so far as I could make out, the vessels terminated in a mass of fibrous tissue in the anterior part of the vitreous. In the present case there is none of this abnormal fibrous tissue formation in the vitreous.

Microphthalmic Eyes with Cystic Protrusions.

The case just recorded is an example of a microphthalmic eye without any defect in connexion with the fœtal cleft; in it the choroid and sclerotic were complete and well formed. In many microphthalmic eyes there is an imperfect closure of the cleft, accompanied by a protrusion of a portion of the retina through the gap Sometimes the protuberant retina becomes distended into a cyst Such a cyst may be so large and the eyeball with which it is connected so small that the latter is clinically completely concealed from view. The apparent absence of the eyeball in such cases has led to some of them being described as cases of anophthalmos, a title which, strictly speaking, is not applicable Of recent years quite a number of records have been published of the microscopical appearances of microphthalmic eyes with protrusions of retinal tissue I have myself recorded the details of seven such eyes, and Kundrat, Rindfleisch, De Lapersonne, Gallemaerts, Czermak, Mitvalsky and Hess have recorded others. A study of the descriptions of all these specimens shows that though they are alike in being microphthalmic eyes with a protrusion of retinal tissue through a gap in the choroid and sclerotic, they present considerable variations, both as regards the character of the protrusion and as to the state of development or mal-development of the other structures of the eyeball. The protuberant portion of retina consists of varying amounts from simply a knuckle of tissue to quite two-thirds of that membrane. In some cases it forms a solid mass surrounded and intermixed with bands of fibrous tissue. In others folds of retina have become distended into one or more fluid-containing cystic protrusions which are bounded externally by a fibrous-tissue coat and have a lobulated outline

The degree of development of the protuberant retina is also very different in different cases. When folds of it have become distended in the form of cystic protrusions it may be so atrophied as merely to be represented by a few groups of nuclear bodies and a little retiform tissue. On the other hand, it may remain so well developed that some of its different layers are easily distinguished. In the latter cases it is found that sometimes the inner surface of the retina is turned towards the interior of the cyst, and at other times just the reverse, the inner surface of the retina being directed towards its fibrous outer wall. The region of the globe in which the protrusion is situated is nearly always its lower and posterior part, sometimes a little further forwards than others. In one case, besides the gap in the sclerotic there was a considerable deficiency in the outer sheath of the optic nerve.

Speaking generally, the larger the amount of the retinal protrusion the smaller and more imperfectly developed is the eyeball. When the protrusion is not very extensive the eyeball may present little external evidence of malformation beyond its defect in size. The lens and vitreous may also appear quite normal. On the other hand, there are numerous congenital defects which may be met with in association with it, such as vascularity of the cornea, formation of cartilage in the sclerotic, coloboma of iris, persistent pupillary membrane, displacement of ciliary processes, cataract, persistence of blood-vessels in the vitreous and formation of fibrous tissue in it, detachments of the retina elsewhere than at the protrusion, and hyaline nodules in the choroid.

In considering the causation of this congenital malformation I would first like to point out that in none of the seven specimens which I have examined is there anything which would lead me to suppose that the changes shown were inflammatory in origin. In one case there were some collections of round cells found in the cyst wall which might have been inflammatory; if so they were of recent production, and as the eye was not removed until the patient was 18 years old they cannot be considered as having had anything to do with the causation of the congenital defect. I lay stress on this point because Deutschmann in 1881, from his investigation of a case of bilateral coloboma of the iris and choroid in a rabbit, advanced the theory, which has been widely accepted and quoted, that so-called arrests of development were only changed developments of the eye the result of intra-uterine inflammation. Hess brought forward several cases which, like those which I have examined, go to show that inflammation has very much less to do with the production of congenital malformations than has generally been supposed. The difference in the position of the retina in these cases suggests that they are not all produced in precisely the same way. When the normal outer surface of the retina is external in the cyst it is possible, as Alt has suggested, that part of the lower wall of the globe, where there was a defect in the choroid and partial defect in the sclerotic, may have been stretched before the intra-ocular pressure and the lining retina pushed into the depression formed. Where, however, the normal outer surface of the retina is towards the interior of a cyst and where the amount of retina which protrudes is very large, such an explanation cannot be accepted, and Kundrat's view, that the cystic formations are due to the projection during development of a portion of the retinal tissue through the fœtal cleft into the subjacent mesoblastic tissue, would seem more applicable. The retina in the human fœtal eye is normally thrown into folds and it is not difficult to understand how, as the result of some imperfect development of the vitreous humour or delayed closure of the cleft, one or more of these folds of the inner layer of the secondary optic vesicle might become extruded through the fœtal ocular cleft into the surrounding mesoblast, and subsequently become expanded into one or more fluid-containing cysts.

A CASE OF INTERSTITIAL FIBROID TUMOUR SLOUGHING "EN MASSE" AND SOME OTHER CASES OF FIBROID TUMOURS OF THE UTERUS.[1]

BY ARTHUR H. N. LEWERS, M.D. LOND.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

AMONG the following nine cases of fibroid tumour of the uterus Case 7 is especially interesting on account of its rarity. It was a case where a large interstitial fibroid tumour situated in the posterior wall of the body of the uterus suddenly sloughed and the sloughing mass protruded, not through the os uteri, but through an opening spontaneously formed in the posterior lip of the cervix. As no operation was done the case may, I think, fairly be classed as one in which a fibroid tumour of the uterus was the direct cause of the patient's death. Such a thing is certainly a rare event, though perhaps not quite so rare as is sometimes supposed. The other cases are interesting chiefly as typical examples of current methods of treatment.

Case 1 was one of uterine fibroids complicated by suppurating ovarian cyst; both sets of uterine appendages were removed, and the fibroid has diminished very much in consequence. Cases 2, 3, and 9 are instances of abdominal hysterectomy with intra-peritoneal treatment of the stump. In Case 3 a point of interest was that the fibroid had undergone cystic change and that one cavity so produced contained puriform fluid. Case 4 was one of pregnancy complicated with large subperitoneal fibroid, in which expectant treatment was adopted with a good result as regards the labour and in which at present symptoms are absent. Cases 5 and 6 illustrate the removal by morcellement of submucous fibroids from the cavity of the body of the uterus after dilatation of the cervix; and Case 8 is an example of myomectomy for large subperitoneal fibroid with intra-peritoneal treatment of the stump. In this case the diagnosis between fibroid and ovarian tumour was doubtful till the abdomen had been opened.

CASE 1. *Suppurating ovarian tumour (left side) and fibroid tumours of the uterus; ovariotomy (left side) and removal of uterine appendages on the right side; marked diminution in size of the fibroid after operation with complete relief of symptoms.*—The patient, a single woman, aged 37 years, was admitted under my care into the London Hospital on Jan. 11th, 1897. She was sent to me by Dr. Deane of Leytonstone. About two years previously she noticed that the lower abdomen was bigger than it ought to be, but she never felt any particular lump there. For the previous two years the quantity lost at the menstrual periods had been excessive and for the previous month there had been a constant sanious discharge. A month previously she noticed swelling of both legs, principally the left, also aching in the legs. Both conditions were somewhat relieved by lying down. During the same time (one month) there had been pain in the lower abdomen, which was chiefly referred to the left iliac region. The catamenia began when she was fourteen years of age and had recurred regularly every four weeks till the beginning of the present illness. The quantity lost was moderate and there was very little pain at the periods; what little pain she had occurred on the first day of the period and was relieved as the flow became established. Her general health had been good till the present illness began.

On admission the patient was found to be thin, sallow-looking, and anæmic. On abdominal examination a hard irregular swelling was felt in the lower abdomen rising out of the pelvis and reaching half way to the umbilicus. It extended outwards to within two inches of the left anterior superior iliac spine. On vaginal examination the tumour in the hypogastric region was found to be the body of the uterus, considerably enlarged, and a good deal less moveable than it should be. There was a softer swelling in the left lateral fornix such as might be produced by a dilated Fallopian tube or a small ovarian cyst. The sound passed three inches and five eighths of an inch with some difficulty. The case appeared to me to be one of uterine fibroids probably complicated by a small ovarian cyst on the left side. The patient was kept in bed for nearly three weeks prior to operation with the view of improving her general condition, and during this time the swelling in the legs became much less marked.

---

[1] A paper read before the Harveian Society of London on Nov. 16th, 1899.

Operation was performed on Feb. 5th, 1897. The abdomen was opened in the usual way. The central tumour, as was expected, was then seen to be the uterus enlarged by fibroids, and there was an ovarian cyst on the left side of the size of a cocoanut, which was intimately adherent to the sigmoid flexure and in the pelvis. During the separation of the cyst it burst and pus escaped. A satisfactory pedicle was obtained and the ovarian cyst was removed in the usual manner. The uterine appendages on the right side were practically normal, but I thought it well to remove them with the object of influencing the uterine fibroids As some pus had escaped during the removal of the cyst the peritoneum was washed out with warm normal saline solution and a drain of iodoform gauze was left in the pelvis; the rest of the wound was closed as usual Examination of the parts removed from the left side showed that the left Fallopian tube was greatly thickened so as to be equal in diameter to the ball of the thumb. No trace of its fimbriated extremity could be seen, the outer end of the tube being firmly attached to the suppurating ovarian cyst, but not communicating with it. The patient made an uneventful recovery and left the hospital on March 6th, 1897.

I have seen the patient on several occasions since and she has remained quite well. There was a slight show about June, 1897; then nothing was seen for nine months, then she had three periods lasting ten days, six days, and four days respectively When I saw her in Feburary, 1899, there had been nothing seen since March, 1898. The case illustrates that the establishment of the menopause after removal of the uterine appendages may be gradual and be spread over an interval of 18 months or two years. The tumour has diminished in size very much. Only on deep pressure can anything be felt of it at all on abdominal examination alone.

CASE 2 *Abdominal hysterectomy with intra peritoneal treatment of the stump; uterus enlarged by multiple fibroids forming a large abdominal tumour extending to the epigastric region, good recovery.*—A married woman, aged 43 years, was admitted under my care into the London Hospital on Nov. 11th, 1898, She was sent to me by Dr Fennell of Tulse hill The patient stated that she had been married five years but had not been pregnant. Her husband was 69 years old. The catamenia began when she was about 15 years of age and had recurred quite regularly till three months previously. She always had lost a rather large quantity at the periods and as a rule they lasted from seven to nine days. Till ten years previously the periods were accompanied by biliousness and sickness. During the three months preceding admission the periods had occurred every fortnight and had lasted a fortnight, so that there had been an almost continuous loss of blood. The last period occurred a month previously and lasted three weeks. There was then a week without any loss and then it began again. There had been no dysmenorrhœa. She first noticed a swelling in the abdomen 12 months previously but thought it was due to flatulence. Six weeks previously she consulted her own medical man as the swelling had rapidly increased. She had noticed that the swelling became larger just before the period and decreased slightly when the flow began. She had lost flesh of late.

On examination the abdomen was seen to be prominent especially on the right side from the epigastrium downwards The surface of the prominence was slightly irregular. The highest point of the tumour was 13½ inches from the pubes measured along the convexity The girth at the umbilicus was 34 inches; three inches lower down it was 35 inches. The umbilicus was level with the skin On palpation a hard irregular tumour was felt rising from the pelvis and reaching the level mentioned above in the epigastric region. One portion of the tumour which measured three inches by two inches just to the right of the umbilicus could be moved rather freely on the deeper seated portion of the mass. The whole tumour could be moved a little from side to side and also about one and a half inches upwards. A well-marked uterine souffle could be heard over various parts of the tumour. On vaginal examination there was seen a good deal of recent blood about the parts. The hymen was tight and the vagina was greatly distended The vaginal portion of the cervix was so much drawn up that the os uteri could only just be touched even when the tumour in the abdomen was pushed towards the pelvis. Under the circumstances I did not try to pass the sound as it seemed impossible to do so without giving the patient an anæsthetic and the diagnosis was obvious without it.

Operation was performed on Nov. 13th, 1898. The abdomen was opened by a long median incision extending from the middle of the epigastric region to within one and a half inches of the pubes. The tumour was then brought outside and the upper portion of the incision as far as the umbilicus was then closed with silk sutures. The upper portion of the right broad ligament was then ligatured in two places and the part between the ligatures was divided. The outer of these ligatures was so placed that the right ovary was not removed. The left broad ligament was treated in a similar way and divided, but on this side the ligatures were so placed that the left ovary remained attached to the tumour and was subsequently removed with it. Anterior and posterior flaps of peritoneum were then made, the flaps being stripped to what was judged to be the level of the internal os uteri. The uterine arteries, which could be well seen, were then tied at this level and the body of the uterus with the fibroids was cut away. The stump consisted of the cervix; its cut edges were approximated with stout silk sutures and the peritoneal flaps were then stitched over the stump by numerous interrupted Lembert's sutures. A Keith's drainage tube was inserted and the rest of the abdominal wound was closed. The patient had some slight rise of temperature during the first few days after the operation, but at the end of the first week the temperature was normal. She subsequently did quite well and she left the hospital on Dec. 14th, 1898.

The tumour weighed 7 pounds 11 ounces some time after it had been cut into and after what fluid it contained had drained away. It consisted of the uterus greatly enlarged by multiple fibroids The cavity of the uterus was much elongated, so that the sound would have passed seven or eight inches The specimen illustrated beautifully every variety of fibroid except submucous fibroids with distinct neck and fibroid polypi; but peritoneal fibroids, interstitial fibroids, and tumours partly submucous were all represented.

I heard from this patient a year after the operation that she was in very good health and during the past year had been able to nurse her invalid husband, which she certainly could not have done in the state of health existing prior to the operation.

CASE 3. *Large abdominal tumour composed of uterus with large sub-peritoneal fibroids, one of which had undergone cystic change with formation of puriform fluid; abdominal hysterectomy with intra-peritoneal treatment of the stump; good recovery.*—A single woman, aged 38 years, was admitted into the London Hospital under my care on Jan. 31st, 1899. She was sent to me by Dr. Surtees Sumner of Guilford street, Russell-square. The patient first noticed a small lump of the size of a pigeon's egg in the right side of the abdomen five years previously. It then caused no pain or inconvenience and she did not trouble to consult a medical man about it. The lump gradually increased in size and about three years previously she thought it moved to the left side. It had increased more rapidly during the last year and had become very hard. She had also had pain in the region of the tumour just before menstruation. On Dec. 31st, 1898, she was seized with a violent attack of pain in the abdomen; she then sent for her medical adviser and she was in bed about a week. The pain was so severe that she could not stand upright. It was relieved by hot flannels and hot-water bottles. She had a second attack of pain similar to the first, but not so severe, a week before admission. Her general health had been as a rule good. In 1892 she had influenza followed by pneumonia and phlebitis During the last year she had lost flesh considerably. Menstruation began when the patient was 16 years of age and she had been quite regular every four weeks, losing a normal quantity and not having much pain. She had not menstruated since November, 1898. On admission the abdomen was found to be irregularly prominent, the most prominent part being at the right of, and a little below, the umbilicus. On palpation the greater part of the abdomen was found to be occupied by a hard irregular tumour. It had a fair degree of mobility from side to side and also slight mobility up and down. Nothing was heard over the tumour. On vaginal examination the hymen was found to be extremely tight and was torn by examination. The cervix was high up, far back, and consequently difficult to reach A hard mass was felt in the anterior fornix, apparently continuous with that in the abdomen; it had some degree of mobility. The sound was passed with great difficulty a distance of three inches.

Operation was performed on Feb. 2nd, 1899. The abdomen was opened by the usual median incision, beginning just below the umbilicus to within one and a half inches of the pubes, but before the tumour could be brought outside the wound had to be extended nearly to the ensiform cartilage. When the tumour had been drawn outside the wound the upper part of the incision as far as the umbilicus was at once closed. The remaining steps of the operation were similar to those in Case 2. The left ovary was not removed.

The tumour weighed nine pounds. It consisted principally of two subperitoneal fibroids of unequal size attached to the body of the uterus, which was moderately enlarged. The larger of these was attached to the uterus by a pedicle so thin that it could be rotated through almost a complete circle The smaller was attached by a thicker, shorter pedicle, but it could be rotated through two-thirds of a circle. The dimensions of the larger fibroid were: length, nine inches; breadth, six and a half inches; and thickness, five inches. The dimensions of the smaller were six and a half inches by four and a half inches by three inches respectively. There was besides a small subperitoneal fibroid of the size of an egg attached to the uterus by a pedicle allowing considerable rotation. The portion of the uterus (body) removed with the tumours was three inches long, three inches broad, and one and a half inches thick. On section, several smaller fibroids were seen in the body of the uterus. On section of the larger subperitoneal fibroid it was seen to have undergone cystic degeneration at one place producing a cavity the cut edge of which measured two and a half inches by three inches. This cavity contained pus. The smaller subperitoneal fibroid showed evidence of commencing cystic changes.

The patient made a good recovery and she left the hospital on March 1st. The scar measured seven and a quarter inches.

I have seen the patient once since she went out. She was then quite well and had then been able to resume her work.

As regards the attacks of severe pain which were noticed prior to the operation it appears probable that they may have been caused by the axial rotation of either of the large subperitoneal fibroids, which, as mentioned above, were very freely moveable on the long axis. The pain might also have been due to a loop of bowel getting nipped between the two large subperitoneal fibroids. The larger of these had undergone cystic change at one place with formation of puriform fluid, and, apart from operation, it is practically certain that other serious symptoms must have arisen before long.

CASE 4. *Large subperitoneal fibroid tumour complicating pregnancy; expectant treatment; normal labour; subsequent moderate diminution in size of the fibroid; absence of symptoms at present.*—The patient, a married woman, aged 29 years, was admitted into the London Hospital under my care on April 25th, 1899. She was sent to me by Dr. Dent of Woodford. She stated that she was married 12 months previously and that up till then she had always enjoyed very good health. The catamenia began when she was 13 years old and she had always been regular every four weeks, the period lasting five days. The last period had occurred in August, 1898. The patient believed herself to be eight months pregnant. About six weeks after the last period she noticed a swelling in the left side of the abdomen; it was not very big but she had to let out her clothes. This swelling gradually increased till January, 1893, since which time it appeared to have remained stationary. About December, 1898, she noticed another swelling in the right side of the lower abdomen (the pregnant uterus), and this had continued to enlarge up to the date of her admission. On Jan. 17th she had a sudden attack of pain in the right side of the abdomen. The pain was very severe and lasted for nine hours She had more or less pain for a week after this and then remained free from pain for a month. She then had another attack of pain, not quite so severe as the first and not lasting so long. Since then she had had similar attacks about once a month and had been obliged to remain in bed since January—i e, three months.

I may say that I saw the patient in consultation with her own medical man in January and I diagnosed a large subperitoneal fibroid on the left side complicating pregnancy, and expressed the opinion that there was no reason for interrupting the ordinary course of the pregnancy. On admission the abdomen was found to be irregularly enlarged. There were two prominences divided by a depression; the larger one to the right was the pregnant uterus. The tumour of the left side extended well down into the flank; it met the pregnant uterus in the middle line and extended as low as a finger's breadth from the left anterior superior iliac spine. It was smooth in outline, hard, and slightly tender. There were various areas of resonance between the uterus and the tumour corresponding to the depression between them. As low as the umbilicus the tumours were easily differentiated, but below that level they appeared to merge into one. On vaginal examination there were the ordinary signs of pregnancy and there was no evidence that the tumour encroached on the true pelvis.

On June 7th the patient was delivered naturally of a female child. There was no post-partum hæmorrhage. On the 17th the highest part of the tumour to the left seemed to be about two fingers' breadth below the ribs in the left nipple line. The uterus lay to the right of this swelling but could not be separated from it. The patient went home on June 21st, 1899, with directions to come to the hospital in two or three months. She did so, and on examination then the tumour to the left had become very much smaller, but still formed a swelling that could be felt in the lower abdomen on abdominal palpation alone. It seemed on bimanual examination to be connected with the uterus and to have all the characters of a sub-peritoneal fibroid. As the patient was feeling perfectly well and not complaining of any inconvenience at all I advised her for the present not to have anything done, but to come up to the hospital again if she had any symptoms.

CASE 5. *Menorrhagia and metrorrhagia due to submucous fibroid of the body of the uterus; marked anæmia; dilatation of the cervix and removal of the fibroid by morcellement and enucleation; good recovery.*—A married woman, aged 38 years, was admitted into the London Hospital under my care on May 13th, 1898. The patient was sent to me by Dr. C. O. Scott of Twickenham She had been married four and a half years but had had no children. There was one miscarriage nearly three years previously, when she was about three months pregnant. This followed a slight accident. The patient had not been quite herself since the miscarriage. Any little over-exertion caused her, as she said, "to come on unwell." The bleeding was stopped if she was able to rest. She was regular if she could rest up to Christmas, 1897. The first period after this lasted a fortnight; since then there had been irregular hæmorrhage, only going a week or two between the losses. She had lost a great deal of blood since Christmas and had had severe pain in the lower part of the back.

On admission the patient was very markedly anæmic, the mucous membranes being very white. On examination slight bleeding was still found to be going on; the uterus was enlarged, but the os uteri was not patulous. A specially prepared laminaria tent was inserted with all antiseptic precautions and the next day the patient was anæsthetised and the dilatation of the cervix completed with Hegar's dilators up to No. 26. The finger was then passed into the uterus and a submucous fibroid of the size of an orange was found attached on the posterior wall of the uterus. Although the greater part of the tumour was no doubt projecting into the cavity of the uterus a considerable portion of it was embedded in the uterine wall. The tumour was removed with considerable difficulty by cutting away piece after piece of it with long scissors and enucleating the embedded portion from the wall of the uterus with the finger. The pieces removed were collected and tied up tightly in a layer of gauze in the shape of a ball, thus giving a very good idea of the size of the tumour within the uterus before the operation. I could not detect the presence of any other fibroid. The patient subsequently did very well; she had no rise of temperature after the operation.

CASE 6 *Menorrhagia and metrorrhagia due to submucous fibroid in the body of the uterus; dilatation of the cervix: removal of the tumour by morcellement; good recovery.*—A single woman, aged 44 years, was admitted under my care into the London Hospital on July 14th, 1899. The patient was sent to me by Dr. McMullen of Brixton. She stated that she was quite well and that menstruation was perfectly regular till two years before admission She then noticed that the loss of blood at the periods was greater than it had been before. This went on for a year and did not affect her much. During the past twelve months not only had the loss at the periods increased but she had had losses of blood between the periods These losses at first only occurred occasionally, but latterly she had had a constant loss of slight quantities of blood between the periods and also she had had a dull aching pain in the left iliac region This pain had been worse during menstruation, especially just before the flow became fully established She had not lost flesh but felt somewhat weaker owing to the constant loss of blood

On examination the uterus was found to be distinctly enlarged In the normal position and freely moveable The external os was not patulous there was a small mucous polypus at the external os of the size of a pea The cervix was dilated as in the preceding case and a submucous fibroid of the size of a Tangerine orange was removed by enucleation and morcellement The patient made an uninterrupted recovery and left the hospital on August 16th

CASE 7 *Septicæmia due to spontaneous sloughing "en masse" of an interstitial fibroid in the posterior wall of the body of the uterus, spontaneous extrusion of a portion of sloughing tumour through an opening in the posterior lip of the cervix manual removal of the remainder, continued septic symptoms and death at the end of three months*—A married woman, aged 40 years, was admitted into the London Hospital on July 20th, 1899 The patient was sent to me by Dr Charles Grant She had been married 12½ years and had had one child eight years previously, but had had no miscarriages The patient had never been really strong, but the present illness dated from Christmas, 1898 The first thing that she noticed wrong was that her menstrual period then lasted three weeks as compared with four or five days its previous duration She sent for her medical man who ordered her to stay in bed and gave her some medicine Between Christmas, 1898, and April, 1899 she had had two similar attacks, each lasting three weeks, and which caused her to feel so ill that she was obliged to stay in bed In April, May, and June the periods lasted longer than they should have done, but the loss was not so great as during the attacks above mentioned I saw the patient for the first time on May 30th and found the uterus enlarged by fibroids so as to form an abdominal tumour reaching nearly to the umbilicus The os was a little patulous but the vaginal portion of the cervix was not at that time at all invaded by any of the fibroid tumours The patient was advised to take ergotin pills and a mixture containing tincture of hydrastis canadensis About the third week in July, some six weeks after I had first seen her, her medical attendant wrote to me to say that the patient had an extremely offensive discharge and that on examination he found the upper part of the vagina occupied by a brittle offensive mass so that he was afraid she had cancer The patient was admitted to the hospital a few days afterwards—i e , on July 20th

On admission she was found to have a horribly offensive discharge and the temperature was 101° F She was very anæmic and looked very ill On examination the uterus was felt reaching to within a finger s breadth of the umbilicus The upper half of the vagina was occupied by a large mass generally convex downwards very irregular in places, and very friable so that it could be easily broken down with the finger Under an anæsthetic a better examination was made The external os was a slit-like opening in front of the offensive mass The os readily admitted the finger The anterior lip of the cervix was very thin with a sharp edge, but the posterior lip could not be recognised as such The sloughing fibroid was not coming through the os at all but had evidently gradually made its way through the whole of the posterior wall of the cervix and had then burst through an opening which had formed on the posterior lip of the cervix itself The sound passed five and a half inches The patient was in a profoundly septic condition, as may easily be understood She seemed to me to be in much the same condition as a patient after confinement where the placenta has not been removed and has decomposed, except that in the present instance the decomposing mass was not in the cavity of the uterus at all, but embedded in the posterior uterine wall except the lowest portion of it, which had burrowed through the posterior lip of the cervix, producing the fungating mass occupying the upper part of the vagina All I did in the case was to remove handfuls of the sloughing mass with the fingers the pieces removed weighing two pounds and eight ounces the manipulation was to some extent like that of removing a putrid placenta The "bed" from which the mass was removed was mopped out thoroughly with tincture of iodine and washed thoroughly with iodine water The cavity of the uterus was also washed out with iodine water The uterus which before removal of the sloughing mass had reached to within a finger s breadth of the umbilicus, contracted down like a uterus after a five months miscarriage so as to lie completely in the pelvis Subsequently for a long time vaginal douches of iodine water were given every four hours and the uterus was also washed out once or twice a day for a considerable time The patient was, however, in a profoundly septic condition on admission, and although she lived for some three months after the expulsion of the mass, fever persisted more or less and she finally died worn out by it

The only alternative in the way of dealing with the case when the sloughing fibroid was found projecting through the posterior lip of the cervix as described would have been to let it alone to come away by itself What the chance of recovery would have been with a putrid mass of tissue weighing two pounds eight ounces embedded for the most part in the posterior wall of the body of the uterus may be easily imagined Although the patient finally died three months afterwards I think that removing the mass as soon as possible gave her the only chance of recovery The case appears to me to be an extremely interesting one for many reasons The spontaneous sloughing and extrusion *en masse* of a large intestinal fibroid such as that described is a rare event, I have not myself in nearly 15 years' experience at the London Hospital met with a similar case Again, the direction in which the extrusion took place—i e , through the substance of the posterior lip of the cervix—is a remarkable thing The more natural direction would seem to be through the mucous membrane of the body of the uterus Whether the course of treatment—of ergotin and hydrastis—had anything to do with the sloughing of the mass I cannot say These drugs are very commonly prescribed in cases of fibroids and for long periods of months and even years without producing any such effect Again, I feel little doubt that if abdominal hysterectomy had been performed when I first saw the case the patient would have been alive now The occurrence of such a case illustrates at all events that what may be called the expectant treatment of large fibroids has certain definite risks and that at present it is impossible to say as regards any particular case whether such an accident as sloughing *en masse* is likely to occur or not

CASE 8 *Large subperitoneal fibroid (five pounds and six ounces) with a thick pedicle, adhesions to several inches of intestine removal of the tumour and uterine appendages on both sides (hydrosalpinx left side), good recovery*—The patient, a married woman, aged 50 years was admitted into the London Hospital on July 31st 1899 She was sent to me by Dr. Spencer of Stoke Newington She had been married 24 years and had had three children, the last 17 years previously She had had no miscarriages Menstruation had always been regular and normal up to the time of admission to the hospital The patient stated that she had noticed that the abdomen had been getting larger for the previous two years and much larger during the previous six months She had also had pain in the right side of the abdomen for some time Her general health had usually been good

On admission a large somewhat rounded tumour was felt occupying the greater part of the abdomen and extending to within three and a half inches of the costal angle The tumour was hard and nearly symmetrically situated as regards the middle line, extending outwards on each side to within a short distance of each anterior superior iliac spine The surface of the tumour was slightly irregular The tumour had a considerable range of mobility from side to side, but less in the vertical direction The circumference of the abdomen at the umbilicus was 36½ inches On vaginal examination a lump was felt bimanually to the left which was taken for the body of the uterus, and the sound passed into this lump a distance of three inches I was not sure whether the tumour was a large subperitoneal fibroid or an ovarian tumour

Operation was performed on August 3rd, 1899 On opening the abdomen the tumour was found to be a large subperitoneal fibroid of the uterus attached to the uterus by a pedicle as thick as the wrist A loop of intestine some eight inches long was festooned across the front of the tumour and was adherent to it by broad membranous adhesions containing large vessels In commencing to separate and tie these the surface of the tumour from which the adhesions were detached bled so freely that it was necessary to put an elastic ligature tightly round the pedicle of the tumour. This controlled the bleeding. After separating all the adhesions peritoneal flaps were made from about two inches above the elastic ligature and the tumour (which weighed five pounds and six ounces) was then cut away. On loosening the elastic ligature the cut surface bled freely, but this was stopped by successive silk sutures passed rather deeply and tied as tightly as possible. The flaps of peritoneum were then sewn over the stump. The left Fallopian tube formed a hydrosalpinx and it was accordingly removed. The right uterine appendages were also removed with a view to check the development of other small fibroids. The body of the uterus in this case was not removed. A Keith's drainage-tube was inserted and the rest of the abdomen was closed in the usual way. The patient did perfectly well. Some months after leaving the hospital she came up again to tell us that she continued quite well.

CASE 9. *Uterus enlarged by fibroids forming a tumour rising to two inches above the navel; portion of the tumour firmly fixed by adhesions in Douglas's pouch bulging down the posterior vaginal wall; abdominal hysterectomy with intra-peritoneal treatment of the stump; good recovery.*—A single woman, aged 29 years, was admitted into the London Hospital on August 8th, 1899. The patient was sent to me by my colleague, Dr. G Schorstein. The patient was a Russian Jewess and could speak very little English, so that the history was obtained with some difficulty through an interpreter. She seemed to have had pain in the lower abdomen more or less for three years. The periods had lasted eight days and during the first three days she had lost a great deal of blood. Her pain was much worse during the period. There had been no intermenstrual loss. I believe the obvious enlargement of the abdomen was one cause of considerable concern to the patient.

On examination a firm, rounded, irregular tumour was felt occupying the lower part of the abdomen and reaching to three fingers' breadth above the umbilicus; it extended outwards some four inches from the middle line on each side. The tumour was fairly moveable from side to side but not vertically. Vaginal examination had to be made under anæsthesia as the hymen was perfect and did not admit the finger without tearing. The os uteri was very high up, about half an inch above the pubes and to the right, it ould only be felt by pressing down the tumour. A hard onvex portion of the tumour lay in the posterior fornix ulging down the posterior vaginal wall to within one and half inches of the vaginal orifice. This mass, which evidently formed part of the abdominal tumour, was practically fixed. The sound could only be passed three inches.

Operation was performed on August 18th, 1899. A large incision was made, which extended some three inches above the umbilicus. A large tumour was found in the fundus and posterior wall of the uterus extending well out to the sides, so as to leave very little room for manipulation. There was a second tumour almost distinct from the first growing from the posterior wall of the uterus and lying in the pelvis to which it was firmly adherent. This was the mass that had been felt lying in the posterior fornix on vaginal examination There was also on the right side an ovarian tumour of the size of a goose's egg. On the left side the ovary was larger than normal and slightly cystic. With great difficulty the upper part of the broad ligament was secured and divided on each side; a peritoneal flap was reflected from the anterior wall of the uterus and the uterine arteries were tied. Owing to the tumour described as growing from the lower part of the posterior wall of the uterus being firmly adherent in the pelvis no posterior flap of peritoneum could be made in this ase. The tumour in question was freed from its adhesions, aving a rather extensive raw surface in the neighbourhood Douglas's pouch It was not till after this step of the eration that the uterus could be drawn out of the wound. e uterus and fibroid tumour were removed at the level of internal os. Both uterine appendages were removed h the tumour. The stump was covered as well as possible h the anterior flap of peritoneum, which had been cut g. A Keith's tube was inserted and the rest of the wound, ch measured seven inches in length, was closed as al. The patient made a very good recovery and left the ital on Sept. 19th. I have seen her once some months wards and she was then quite well.

ley-street, W.

ON THE RESTORATION OF COORD MOVEMENTS AFTER NERV SECTION.[1]

BY ROBERT KENNEDY, M.A., D.Sc., M.D.

IT is now well known that after reunion of a nerve by means of suture function may return later, and that not only does this restoration of imply simple return of sensation and of the cap making voluntary movements, but the re-establ of complete localisation of sensation and of coord of movements. When it is remembered that th vidual nerve fibres are supposed to be paths b well-defined centres and peripheral endings it is that so perfect a restoration of function is in respects remarkable. Thus in coapting a divided it is not likely that this can be effected wit great accuracy that the corresponding ends of divided nerve-fibres can be brought into apposition. more likely that in coapting the nerve most of the ends of nerve-fibres which are brought into contact are ends wh do not correspond; and thus it would be expected tha the reunited nerve new paths for the nervous impulses wo be established. And yet, despite this complexity of structu and of function, the reunited nerve seems to be as capable before the division of subserving its functions. In sutur divided nerves, care is usually given to secure that the tw segments are approximated as nearly as possible in their ol relationship Thus the perfect recovery of localised an coordinated function might be due to a majority of the fibres being thus placed in a position for union of corresponding ends to take place.

To investigate this subject, three experiments were performed on dogs, the sciatic nerve being chosen. In two experiments the peripheral segment, before reunion by means of suture, was twisted so as to bring the maximum number of non-corresponding nerve-fibre ends into juxtaposition, while in the third experiment reunion was made as accurately in the old position as possible. The object of this was to ascertain (1) if the time taken for the first evidence of recovery of coordinated movements and the course of development of the same were identical or different in the two cases; and (2) if the resulting cicatricial nerve segments showed microscopically any important differences in the arrangement of the nerve-fibres. In all three experiments, the animal being anæsthetised, the sciatic nerve was divided at the level of the trochanter; but in the first two, before coapting the two ends by suture, the peripheral segment was rotated to the extent of a semicircle. Thus, on coaptation, the fibres of one side of the central segment were brought into apposition with fibres with which formerly they did not connect—i e., the fibres of the opposite side of the nerve. In the third experiment the nerve was divided at the same point and accurate coaptation in the old relationship was effected by suture. The following is the course which the experiments exhibited with reference to recovery of function.

EXPERIMENT 1 *Division of the sciatic nerve at the level of the trochanter; rotation of the peripheral segment to the extent of a semicircle and suture.*—Until the seventh day after the operation the animal showed no sign of returning function. It walked on the limb which was supported by plaster-of-Paris bandages. The paw was left unsupported for examination purposes and until the seventh day while the animal walked on the limb the paw was dragged along the ground with the dorsal surface down. But on the seventh day the paw was first used normally in walking, the plantar surface being placed correctly on the ground. This was taken as evidence of returning coordinated movements. Frequently while walking the paw turned over and the animal rested on the dorsal surface, but on these occasions the normal position was voluntarily regained after a step or two. Restoration of localised sensation could not be ascertained, but undoubted evidence of sensation was obtained on the tenth day. On the fourteenth day the supporting plaster-of-Paris splint was removed and the wound was found to be healed. The animal then used the leg perfectly, almost always placing the plantar surface of the paw on the ground correctly. By the nineteenth day the dog had practically completely recovered from the effects of the operation. On the fifty-fourth day the nerve was again exposed and was found to be united in the position in which it had been sutured. Stimulation above, below, and on the seat of reunion gave the normal contractions in the muscles of the leg.

---

[1] The research is published *in extenso* in the Transactions of the Royal Society of Edinburgh, vol. xxxix., No. 27, 1899, and was communicated by Professor McKendrick.

EXPERIMENT 2. *Division of the sciatic nerve at the level of the trochanter; rotation of the peripheral segment to the extent of a semicircle and suture.*—In a few days the animal was walking about on its splinted leg, but dragging the paw along the ground with the dorsal surface down. On the seventh day it was first noticed that the plantar surface of the paw was correctly placed and, although occasionally turning over on the dorsal surface, it was on these occasions voluntarily replaced in position after two or three steps. By the twenty first day distinct evidence of sensation was exhibited and the recovery of the normal use of the limb was practically complete The physiological examination of the nerve on the thirtieth day showed it to be united in the position in which it was sutured and to have regained its normal irritability and conductivity.

EXPERIMENT 3. *Division of the sciatic nerve at the level of the trochanter; accurate coaptation by suture in normal position*—On the seventh day the animal first showed signs of recovery of function, as for the first time it was then noticed that it walked placing the plantar surface of the paw on the ground. It was not, however, able voluntarily to re-adjust the paw when it happened to turn over with the dorsal surface down. This power was, however, exhibited on the following day. By the eleventh day evidence of sensation was obtained and by the fourteenth day the recovery of function was complete. On the forty-ninth day the physiological examination showed that reunion of the nerve had taken place both anatomically and physiologically.

As regards recovery of function, therefore, these three experiments followed a practically identical course. The microscopic examination of the three sciatic nerves showed the following characters. The central segments showed the characters of the normal sciatic nerve, except in so far that the lymphatic spaces were somewhat distended, thus accounting for the increased thickness of the nerve which was macroscopically evident This character was maintained to within five millimetres of the seat of section. The peripheral segments agreed in showing no old nerve fibres in any part examined either close to the seat of reunion or in the terminal divisions of the nerve. In their place were abundant young nerve-fibres with well-defined characters. Lying between the young nerve-fibres were degenerated remains of the old fibres, showing that Wallerian degeneration had taken place. The cicatricial segments were also all three practically identical in structure. In no case could continuity of nerve-fibres from the central to the peripheral segment be traced in a single section. The arrangement of the young fibres was very irregular, the fibres running a very tortuous course and showing, therefore, in the section cut in all directions. The sections closely resembled the appearance of a neuroma. The microscopic appearances of the seat of reunion leave it, therefore, doubtful whether the restoration of function in the two first cases was due to the re establishment of the old paths for the nervous impulses by decussation in the cicatrix, or to the production of new paths by connexion made between non-corresponding ends of nerve-fibres.

The conclusions from the physiological and histological results of the experiments are. 1. That after section and immediate coaptation of a nerve, restoration of conductivity and of voluntary function may be effected in a few days. 2. That this early restoration of conductivity need not be the result of reunion of the old nerve-fibres—i e, reunion by so called first intention, or without Wallerian degeneration, but may be the result of regeneration of young nerve-fibres in the peripheral segment. 3. That voluntary coördinated movements are regained equally soon, whether the two ends of the divided nerve are united as accurately as possible, so as to bring the corresponding ends of the nerve-fibres into contact as nearly as possible, or whether previously to reunion the peripheral segment is twisted so that when united to the central segment non corresponding ends of the nerve-fibres are brought into contact. 4. That in the latter case the microscopic examination of the seat of reunion leaves it doubtful whether the restoration of function is due to the re establishment of the old paths by decussation in the nerve cicatrix or to the reunion of ends of nerve fibres which do not correspond but which happen to be brought into apposition. 5 That in suturing a divided nerve no trouble need be taken to secure that coaptation of the two segments is effected in the old relationship, the simple approximation of the two ends, no matter in what relationship, being all that is required.

Glasgow.

A BRIEF REVIEW OF OUR KNOWLEDGE CONCERNING BACKWARD DISPLACEMENTS OF THE PELVIC ORGANS.

BY FREDERICK HOLME WIGGIN, M.D.

THE most frequent causes of displacements of the pelvic organs are injuries of the perineum occurring during childbirth and septic infection of the uterine tissues, generally due to one of three causes—namely, abortion, gonorrhœa, or the intra-uterine use of unsterilised instruments. Could these etiological factors be done away with—and in time let us at least hope that they will be, for all of them are either preventable or amenable to proper methods of treatment—there would be little left for the gynæcologist to do, and womankind, to say nothing of mankind, would be not only benefited but made happier thereby. As anterior uterine displacements are seldom pathological we will pass them by and come at once to backward displacements of the organ. These may be congenital or they may occur during early life as a result of an improper mode of life, of the use of improper clothing, of falls, blows, the lifting of heavy weights, and, I believe, more frequently still from neglect to empty the bladder at proper intervals of time, the over-distension of this viscus tending to push the uterine body backward. In married women the trouble is chiefly due to injuries of the perineum and inflammatory disorders of the uterus, tubes, and ovaries. Retroflexion of the uterus occurs generally after the occurrence of septic infection following an abortion or childbirth, and is frequently due to the fact that the convalescence following these conditions is not sufficiently prolonged.

The symptoms which patients complain of who are suffering from backward uterine displacements are backache, more or less severe, referred to the upper portion of the sacrum, a feeling of weight extending down to the thighs, general bodily weakness, inability to stand long or walk far, pain at the top of the head and in the ovarian region, dysmenorrhœa, leucorrhœa, and frequently menorrhagia.

The diagnosis must of course be finally made by means of a bimanual vaginal or rectal examination, with the patient in the dorsal position, the patient having first been requested to empty her bladder. When the finger is introduced into the vagina if this condition exists the cervix will be found to point either towards the symphysis pubis or to lie parallel to the long axis of the vagina instead of being at right angles to it, as it should. Often more useful information about the pelvic organs can be obtained by means of a rectal examination than by a vaginal one, and in unmarried women it should always be first made.

The treatment of backward uterine displacements may be either by the use of mechanical supports or by operative means. The former method of treatment is less often used than it formerly was, as it is palliative rather than curative. It is indicated only in those cases where the condition is due to relaxation of the tissue and ligaments, or where operative measures are contra-indicated or declined. It should not be used in any case where there is a laceration of the cervix or any inflammatory disease, past or present, of the uterus and its appendages, or where there is a prolapse of one or both ovaries. If it is determined to adopt this line of treatment the patient should be placed in the knee chest position, the posterior vaginal wall retracted, and the cervix exposed by means of a Sims speculum. The cervix is next—after having been washed off with a mercuric chloride solution of 1 in 4000—grasped by a double tenaculum forceps and drawn down. The fundus is next pushed towards its proper position by means of uterine dressing forceps in the jaws of which a piece of cotton is held. The organ having been returned as nearly as possible to its proper position should be retained there by means of pledgets of cotton, wet with a boroglyceride solution, packed into the posterior vaginal fornix, and other pieces placed anteriorly to the cervix. This packing should be removed on the following day and a douche given, the patient lying on her back. The procedure just described is then to be repeated daily for several days, when the uterus can generally be retained in position by means of a hard rubber pessary. While this instrument is being worn the patient should take a daily douche in the dorsal position and she should be under the observation of her physician. If the instrument causes discomfort or pain it should be at once removed, as these symptoms indicate that the instrument is not adapted to the patient, or that she should not be treated in this manner. After the instrument has been worn for three or four months it should be removed, and the patient should be examined at short intervals of time to see whether the uterus remains in its proper position or not. If the displacement soon recurs the pessary must be at once replaced and the patient informed that she will either be obliged to wear the instrument permanently or submit to operation.

Of the surgical procedures devised to rectify backward uterine displacements giving rise to symptoms the best in my opinion is that which was first described by Mackenrodt of Berlin, and which was known by the name of "uterine vagino-fixation." The simplicity of its technique, he safety, ease, and rapidity with which it can be performed, s well as the good results obtained, make it a valuable eans of relief for these patients. Before the operation is performed the uterus should be replaced, as already described, and the patient should be kept in bed for several weeks, her bowels meanwhile being thoroughly unloaded by means of small doses of cathartic medicines and high enemas of saline solution. The patient is then prepared as for a vaginal hysterectomy, and being under the influence of an anæsthetic agent is placed on the table in the dorsal position with the thighs flexed and held in place by means of a Clover crutch. The cervix is then exposed by means of a weighted speculum and is drawn forward by means of a tenaculum forceps. As in this class of cases there is more or less endometritis it is well to begin the operation by curetting the uterus with a sharp curette, gauze not being placed in the cavity. Any existing laceration of the cervix should be repaired, sutures of chromicised catgut being used. These steps having been taken, the cervix is grasped and then drawn downward and forward by the aid of a pair of bullet forceps. Then a portion of the anterior vaginal wall about three-quarters of an inch below the meatus urinarius is taken up in the same way and drawn forward and upward, thus stretching the wall. An incision is made, beginning at the last-named point and continuing to the cervix. If this wall is more or less prolapsed the incision, instead of being straight, should be oval, allowing for the removal of sufficient tissue to overcome this defect when the sutures which close the vaginal wound are placed. These flaps are dissected from the inferior surface of the bladder, into which a sound is passed and by its aid the thickness of the bladder-wall is estimated and its lower border defined. A needle threaded with pedicle silk is passed through the inferior edge of either flap and tied, the ends being kept long. These serve as retractors, and the flaps being held aside a curved transverse incision is made at the cervico-vesical junction. The bladder is freely separated from the uterus by blunt dissection with the finger, the vesico-uterine fold of the peritoneum being divided by the aid of scissors. The patient's hips are elevated, which allows the bladder and intestines to gravitate from the uterus, the fundus of which is brought into view and is seized by a pair of bullet forceps and drawn forward. The ovaries and tubes are inspected after any existing adhesions have been broken up and if the organs on both sides are found to be diseased it is best to remove the uterus with them. If, however, the diseased condition is unilateral, the parts involved are removed and the uterus is left. A suture of chromicised catgut is next passed by means of a curved needle through the left vaginal lap, at a point slightly distant from its superior margin, hen through the muscular tissue of the anterior uterine all close to the fundus, and then through the right vaginal ap near its upper margin. A second suture is passed the same way about one-third of an inch below e first. The uterus being well anteverted, the sutures e tied loosely. The rest of the wound in the terior vaginal wall, after free irrigation with ne solution and the application of hydrogen dioxide if there is much oozing, is closed by mean sutures of horsehair or catgut, and the wou painting it over with a 10 per cent. solution ether. A small quantity of gauze is placed in the purpose of effecting drainage, and an ant applied to the vulva. The time occupied by th usually 20 minutes. The patient's urine is dr of a new catheter (which should preferably be glass, to which is attached a rubber tube) t voided voluntarily, which is generally at the third day. The vaginal gauze is removed abo and is not replaced. A daily douche of weal solution is given, after which the iodoform solut painted over the wound. The vaginal sutures a at the end of a week or sooner if they begin tissues. The patient is retained in the horizont for three weeks and then is allowed to assume posture. At the end of the fourth week she is pe leave the bed and move about and soon thereafter t her ordinary duties.

The left ovary is more frequently prolapsed than t The condition may be of congenital origin, or it ma from a sudden strain, but its most frequent cause, w carried down by a displacement of the uterus or Fallopian tube, is undoubtedly sub-involution. Wh organ lies at the bottom of Douglas's pouch betwe posterior vaginal wall and the rectum the patient plains of dyspareunia, and of pain when standi walking and during and after defecation. This which is referred to the inguinal region and ra down the thighs, often lasts for several hours. The disturbances which accompany this condition are ma and all symptoms are increased during the mens period. The disorder is usually diagnosed without diffic by a bimanual examination of the pelvic organs, wh if the ovary is not found in its normal place to right or left of the uterine body, the examining fing which should be the right or left according as the patien right or left side is to be examined, is carried high behind the cervix and its palmar surfaces gradually turne downward, when the organ if displaced downward ca generally be easily felt and pressed against the sacrum When this is done, if the body felt is the ovary the patien will complain of a sickening sensation, or it may be found near the vaginal outlet. Of course, it is hardly necessary t say that these examinations in order to be successful should only be made after the thorough emptying of the patient's intestinal tract. When the malposition of the organ is due to a displacement of the uterus the correction of this difficulty will generally relieve the trouble. When the prolapse is due to congestion or sub-involution the organ should be replaced by means of the knee-chest position and retained there by tampons of cotton wet with boroglyceride solution. These should be removed daily and followed by prolonged vaginal douches of hot water, the patient lying on her back during this procedure, after which the tampons are to be re-applied. While this is in doing the patient's bowels should be kept relaxed and much benefit is often derived from rest, general tonic treatment, and massage. When, however, these mild measures after a reasonable trial do not suffice operation is demanded, and oöphorectomy is often avoided by drawing the ovary back to its proper position and holding it there by means of a few stitches taken through the ovarian and broad ligaments. This procedure can be accomplished either by means of a small abdominal incision or by the one already described through the anterior vaginal wall, which I much prefer.

There are few ills, if any, that womankind is subject to, other than malignant disease, which produce greater disability and discomfort than procidentia of the uterus, accompanied as it is, in the first instance, by chronic inflammatory changes of the organ and by the displacement of both bladder and rectum, with marked interference of their functions, this often being followed by cystitis and proctitis. The condition under consideration is that of a reducible hernia through the pelvic floor and, as is well known, the most frequent cause of the difficulty is an unrepaired rupture of the perineum and inability or carelessness on the patient's part to confine herself to bed for a proper length of time after the birth of her child, thus causing a strain on the relaxed ligaments of the enlarged and heavy uterus. Therefore, it may be said that we have, first, a damaged perineum, accompanied by constipation, then a rectocele, then a cystocele, and finally the gradu escape of the uterus from the body. The sign of the disease is a local tumour, and the chief symptoms are backache, bearing-down pains, difficult and painful micturition, and more or less inability to walk. To determine the degree of prolapse the patient is suffering from she should be examined both while standing and in the dorsal position, and should be encouraged while in the latter posture to strain or bear down, a piece of cotton being meanwhile held firmly over the anal orifice to prevent escape of fæcal matter or gas. The patient on coming under control should be placed in bed and the parts reduced and held in position by tampons previously moistened with boro-glyceride solution, attention being paid to the intestinal canal and bladder. The mechanical devices for the relief of the condition are numerous. The best may be said to be Gehrung's pessary and Braun's colpeurynter, but in my opinion the treatment in a majority of instances should be in the line of restoration of the damaged parts to their normal condition. If the patient is seen before the uterus has descended very far an operation on the posterior and anterior walls, combined with curettage, may suffice, but when the prolapse is complete additional means must be employed if we would permanently retain the displaced parts in their proper place. The patient having been prepared in the usual manner and placed under the influence of an anæsthetic agent in the proper position, and the cervix exposed and drawn down, as previously described, the uterus is to be thoroughly curetted. The cervix if lacerated and indurated is to be amputated, after which the anterior vaginal wall is incised, the bladder is separated from the uterus, the peritoneal cavity is opened, and the fundus of the uterus is brought forward and attached to the anterior vaginal wall in the manner already described. The necessary portion of this wall, to correct the cystocele, should at the same time be removed. After the wound is closed the perineal injury should be repaired. For some time past I have done this by a method which consists of bringing the separated muscular structures together by means of buried sutures of kangaroo tendon, which by not passing through the mucous lining of the vagina lessen the danger of infection and hold the parts firmly together for several weeks after the wound has healed. Where the degree of prolapse of the uterus is great, I have been in the habit for several years of first opening the peritoneal cavity by means of an abdominal incision, the patient being placed in the Trendelenburg posture and after drawing the uterus up to its proper position fastening it there by means of stitches placed on either side through the broad and round ligaments, thus giving the uterus new supports on either side near the pelvic brim. After closing the abdominal wound the uterine cavity is to be dilated and the organ curetted and whatever is necessary is done to repair the damage to the anterior and posterior vaginal walls. In some cases where the patient is near the menopause and the uterine body is much enlarged it is well to amputate it near the internal os and to proceed as before. In old and feeble women good results have been obtained by me by means of the following procedure, first described by Fritsch, which can be done under local anæsthesia. The cervix is seized with a double tenaculum forceps and drawn forward and a buried suture of kangaroo tendon is carried round the vagina a little above the cervix, which is then to be pushed up. The suture, the ends of which emerge from the same opening, is then drawn tight, tied, and the ends cut off short, causing the knot to disappear from view and to be buried in the tissues. This procedure is to be repeated until six or more similar sutures are placed encircling the vagina at various points, which will result in an entire obliteration of the prolapsed tissue and of the greater portion of the calibre of the canal. The perineum is next to be repaired and the wound protected in the usual manner. At the end of three or four weeks the patient is allowed to be up.

My chief aim in this paper has been to show that displacements of the pelvic organs are largely an unnecessary ill, due to preventable causes. Mothers should be told to instruct their daughters as to the importance of a proper mode of life, of the use of proper clothing, of emptying the bladder at proper intervals, of the danger of falls and of lifting heavy weights. After parturition we should always at once examine our patients for the purpose of finding out whether or no any local damage has been done, and when any is done it should be at once repaired. We should also encourage them to "make haste slowly" during convalescence and not to resume ordinary labours till the pelvic organs and parts have had time to regain their natural size and condition. They should be advised further to return within three months after confinement in order that a careful local examination of the cervix can be made, and more care should be taken than is often done to sterilise the hands, instruments, vagina, and cervix before exploring the uterine cavity.

Women should be taught that miscarriages, abortions, and venereal disease bring their own penalty and that they are seldom as well after the occurrence of these mishaps as before; even so, much can be done to limit these troubles and lessen their after-effects by their prompt recognition and intelligent treatment.

New York.

DIPHTHERIA OF THE CONJUNCTIVA.

BY SYDNEY STEPHENSON, F.R.C.S. EDIN.,

OPHTHALMIC SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN, TO THE *NORTH-EASTERN HOSPITAL FOR CHILDREN*, AND TO QUEEN CHARLOTTE'S LYING-IN HOSPITAL, &c.

IN my experience ophthalmia associated with the Klebs-Löffler bacillus is far from rare in London, although it must often escape recognition unless a routine bacteriological examination be carried out. At the North-Eastern Hospital for Children, where such an investigation is adopted in every doubtful case, we see instances of the disease pretty frequently. Mr. C. G. Burton,[1] the resident medical officer at that hospital, in the course of a recent communication to THE LANCET, calculated that of all the cases of ophthalmia taken there for treatment 2 per cent. belonged to that category. This estimate agrees with our later experience. The cases run in groups, and are more common when ordinary diphtheria is prevalent amongst the poor of East London. Children over three years of age are seldom attacked. On the other hand, the classical conjunctival diphtheria described by Graefe is practically unknown at the hospital and that seems to be the general experience throughout the country. According to figures quoted by Professor Fuchs in his monograph on "The Causes and Prevention of Blindness" diphtheria of the conjunctiva was present in 0.2 per 1000 only of 22,130 patients who were seen at the Royal London Ophthalmic Hospital in Moorfields. It may be presumed that such an estimate includes only cases so extreme that they can scarcely escape recognition. The brawny and board-like lids, the lardaceous and ecchymosed conjunctiva, the depressed patches of false membrane, the rapid destruction of the cornea, and the marked general symptoms make up a clinical picture that once seen cannot be readily forgotten. The other cases, which have long been termed "croupous," vary much in intensity. The lids, however, can be everted and the false membrane detached without much difficulty, the cornea may or may not suffer, and general symptoms are more often absent than present. The disease presents a close resemblance to a common diphtheritic affection of children, viz., fibrinous rhinitis, where constitutional symptoms are practically unknown, although the nares may be the seat of false membranes teeming with diphtheria organisms.

It would therefore appear that croupous conjunctivitis bears much the same relation to diphtherial conjunctivitis as fibrinous rhinitis does to nasal diphtheria. Indeed, even before the advent of the bacteriological era it was conjectured by acute observers that the two forms of ophthalmia mentioned above were at root one and the same disorder—viz., diphtheritic inflammations of mild and of severe type. Faucial diphtheria was known to have been contracted from so-called croupous ophthalmia. Cases of that kind have been cited by Schirmer and by Haab. The mere existence of a membranous exudation on the conjunctiva is in itself no evidence of a diphtheritic process, but the presence of such a product should at once suggest a bacteriological examination. As I have pointed out elsewhere[2] the finding of the Klebs-Löffler bacillus is the only certain way of recognising the disorder, and in my opinion a diagnosis of conjunctival diphtheria should never be made in the absence of such evidence.

It follows from what has been said that the existing ained facts. It aside the ambiguous term to classify cases into mild or severe, or even adopt the anatomical basis of certain continental writers who recognise (1) the superficial membranous cases, (2) the interstitial cases, and (3) the catarrhal cases. Since it has been shown that diphtheria of the conjunctiva need not of necessity coincide with a membranous exudation, there is good ground for belief in the existence of the so-called "catarrhal" cases. The remaining forms of conjunctivitis with membrane would naturally be classed with reference to the micro-organisms present, such as the pneumococcus, &c.

[1] THE LANCET, Jan. 20th, 1900, p. 227.

[2] Brit. Med. Jour., June [illegible]th, [illegible]

Our practice with regard to treatment is to inject an adequate dose of antitoxin if we suspect diphtheria, without losing valuable time by awaiting the results of a bacteriological investigation. We do not hesitate to allow the patient to be taken home after the injection, but should the specific microbe be subsequently found, we detain the child in the diphtheria ward until cured. As to local means we generally employ a strong solution (15 per cent.) of potassium permanganate to paint over the exposed conjunctiva once a day and a weak antiseptic lotion, such as corrosive sublimate 1 in 5000, for cleansing the mucous membrane at frequent intervals. Should the cornea be involved atropine drops (two grains to the ounce) are used from three to six times a day.

The following case, besides presenting one or two points of special interest, is fairly typical of the milder type of conjunctival diphtheria.

A boy, aged two and a half years, was brought to the eye department of the North-Eastern Hospital for Children on Sept. 28th, 1899, with the statement that his left eye had been inflamed since the 23rd. He was well nourished and did not look particularly ill. The lids of the left eye were markedly swollen and of a violaceous hue, and there was abundant muco-purulent discharge from the palpebral fissure. On everting the palpebræ (which could be done without much difficulty) a membrane was observed on the con-unctiva, upper and lower. Although thicker upon the lower d than elsewhere it could be easily peeled away. The vollen ocular conjunctiva was free from false membrane. é cornea was cloudy without actual ulceration. The lp showed several impetiginous areas, one of which had en freed from scab at home and was covered, when mined at the hospital, with an adherent grey membrane. erous discharge was present from the nostrils, but no s of diphtheria could be made out either there or in the at. The pre-auricular and angular glands were enlarged. min was present in the urine. The temperature was ., the pulse was 104, and the respirations were 24. e child was admitted to the diphtheria ward, and 2000 of the Royal Colleges of Surgeons and Physicians' xin were injected. The conjunctiva was painted a day with potassium permanganate (15 per cent.) and es were kept clean with a saturated aqueous solution ric acid. The scalp was treated with ammoniated y ointment (five grains to the ounce). Cover-glasses neared with particles of false membrane, which was bed over the surface of blood-serum and agar-agar. The film-preparations, when stained and examined microscope, showed many long bacilli, often curved uped side by side. They stained with Gram's They seemed to be the specific organism of diph-On the media, after incubation for 24 hours, fine vere obtained not only of Klebs-Löffler bacillus but taphylococcus albus and staphylococcus aureus. ltivations were made from the membranous patch alp and staphylococci and (?) diphtheria bacilli

On Oct 6th it was found that the corneal haze present on admission had given way during the ur days to a circular ulcer of that structure. ops (½ per cent.) were prescribed thrice a day. h the membrane was absent from the red and njunctiva. The ulcer on the cornea was neither or were its edges undermined. The patch of n the scalp had healed. On the 20th the junctiva, although congested, was not markedly ere was a slight discharge from the eye. The had healed with the production of a nebula. s discharged on the 20th, after a stay in the days. For the greater part of that time the mained about normal, but a slight rise took eventeenth day, probably as the result of the titoxin.

W.

A SUCCESSFUL CASE OF CŒ FOR INTESTINAL OBSTRUCTION TO PERSISTENT MECKEL' DIVERTICULUM.[1]

BY CHARLES A. MORTON, F.R.C.S. EN
PROFESSOR OF SURGERY IN UNIVERSITY COLLEGE, BRISTOL
TO THE BRISTOL GENERAL HOSPITAL AND TO THE BRI
ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN

THE case which I am about to describe seems to of special interest for two reasons: first, the the disease was quite unlike that of acute in obstruction, and, secondly, the way in which the diver caused obstruction was an unusual one.

The patient was a girl, nine years of age, and wa to me by Mr. F. E. Peake. The illness began w complaint of any abdominal pain. On July 31st, the child began to suffer from headache and vomiting she was kept in bed. On the following day, althoug vomiting persisted, she was up and about. It was not August 2nd—the third day of her illness—that abdom pain situated in the umbilical region was first complai of. The patient continued to vomit frequently and got m worse on the 4th, and when seen by me on admission to hospital at 3 P.M. on the 5th she was obviously very ill w a distended abdomen and dry, brown tongue. The pul however, was only 100, and the temperature was betwe 99° and 100° F. She cried out every now and again with pa in the abdomen but did not vomit at that time. Thre visible coils could be seen in the distended tympaniti abdomen, but they did not contract or dilate with peri stalsis. There was some general tenderness, but the abdo minal walls were not rigid. There had been no passage of blood or mucus from the bowel. No reliable information could be obtained as to when the bowels had acted last or as to the passage of flatus. There was a history that 18 months before she had had an attack of abdominal pain and vomiting lasting for two days but she had not been laid up by it.

The onset of the illness was certainly not like that of acute intestinal obstruction. It was more suggestive of an attack of appendicitis, but the general distension of the abdomen and the evidently serious condition of the child were such that one could not help suspecting that if the disease had begun as a localised appendicitis it had, at any rate at the time of her admission to the hospital, become complicated with a general peritonitis; and yet the abdominal wall was not so rigid as it is usually found in a condition of general peritonitis, nor is visible distension of a few separate coils seen, as a rule, in such a condition. But these coils were not observed to harden from peristalsis, as they so often do in mechanical obstruction. If I had observed this condition in the distended coils I should have felt sure that it was not paralytic distension from peritonitis but some form of mechanical obstruction. The temperature is, I think, of little guide in such cases. It may not be raised at all in the severest forms of septic peritonitis, and, as in this case, may be slightly raised in mechanical obstruction. Whatever the exact condition might be, however, it was clear that there was an acute abdominal condition which demanded immediate operation, and at 5 30 P.M. on the day of admission I operated. On opening the abdomen a considerable quantity of clear serous fluid poured out of the pelvis. A large extent of the small intestine was found to be considerably distended, but some empty coils were at once discovered, and on tracing one of them it was found to pass within a ring of what felt like bowel, and when drawing this to the surface by traction on the empty coil the latter slipped out of the constriction together with a distended portion of bowel, and between the two was seen the groove of constriction. After the liberation of the strangulated bowel it was found that the constricting ring into which the bowel had slipped was formed by a persistent Meckel's diverticulum. The bowel had been strangulated beneath the diverticulum which passed from the ileum at the usual spot to the umbilicus.

Mr. Treves,[2] who has fully investigated the which the diverticulum persists and the mode in which it causes strangulation, says that it is difficult to understand how the bowel can be strangulated under the diverticulum when it extends from the ileum to the umbilicus, and that in nearly all cases in which the strangulation has occurred beneath the diverticulum it has been adherent to some structure other than the umbilicus, usually the mesentery; and he suggests that when the bowel has been said to be strangulated beneath the diverticulum, passing from the ileum to the umbilicus, the condition has probably been one of volvulus in a coil caught under the diverticulum. Therefore, it is interesting that in this case the strangulation did take place beneath a diverticulum passing from the ileum to the umbilicus, and that the groove of constriction on the bowel showed that the obstruction had been caused by strangulation and not by volvulus. I cannot deny that a loop in the diverticulum may possibly have snared the gut and that in drawing out the constricted bowel I may have destroyed the loop. All I can say is that I saw no evidence of such a loop and I think that had there been one I should have observed it.

---

[1] A paper

I excised the diverticulum. It began as a funnel-shaped projection from the ileum of an inch and a half in length and terminated in a round cord attached to the umbilicus. Before excision I applied a clamp to the diverticulum at its attachment to the duodenum, for it had a diameter here of three-quarters of an inch, and then united the margin with Czerny-Lembert sutures. The umbilical end I simply ligated before division The region of the peritoneal cavity in which the stump of the diverticulum lay was drained for a few days to guard against any risk of peritonitis from leakage, which did not, however, occur. The child made an uneventful recovery.

Clifton, Bristol.

A HEPATIC MUCOID CYST.

BY W. CAMPBELL M'DONNELL, M R.C.S. ENG., L R C.P. LOND.

THE following case seems to be worthy of record by reason of the rarity of hepatic single cysts, not hydatid. The patient was a man, aged 53 years, giving a history of severe, sudden, recurrent epigastric pain extending over several years, and I saw him in what was apparently one of these attacks. Tenderness of the whole abdomen developed with pyrexia and the pain increased till death. At the post-mortem examination there was general purulent peritonitis resulting from an old ulcer situated at the pyloric undersurface of the stomach, adherent to the pancreas. Some gastric contents had extravasated and set up the peritonitis. Mr. C. H. Jackman kindly saw the patient with me, and it is owing to his courtesy that I am able to reproduce the appearances of the microscopical section shown below.

On the mid-upper surface of the liver there was a spherical tumour, 9·5 centimetres in diameter, firmly adherent to the diaphragm, less adherent to the inferior vena cava, removeable from the liver without tearing the cyst but exposing an irregular liver surface similar to that of a kidney markedly affected by chronic Bright's disease. There was no renal cyst. The cyst wall was smooth, tough, fibrous, white on section, and 1·5 millimetres thick. The main bulk of the cyst was a firm, pale apple-green jelly, of specific gravity 1029, which was found to be mucin. Through the mucin were sparsely scattered red, brown, or yellow seed-like bodies which in some instances were accumulations of hæmin crystals; in others small masses of shrivelled red blood cells with a few hæmin crystals cemented together by a bright yellow mucin. At one spot there was a small opening in the interior of the cyst wall connected indirectly with a dilated vein of the exterior cyst wall by a long oblique piercing of the wall. At that place there was seen a layer of old blood and of dark seed-like bodies in their greatest accumulations. The mucin had in it many tufts and clusters of tyrosin and a large number of variously-sized cholesterin plates; it contained a small amount of albumin and was devoid of cells; it did not give Pettenkoffer's bile acid reaction or the iodine colour reaction of bile pigments A solution of the jelly in strong nitric acid reduced Fehling's solution very readily. From the slowly evaporated solution and re solution of the residual paste in distilled water chlorides and sulphates were precipitated, the former in large, the latter in much less, quantity; from this solution urea was prepared in crystals. The insoluble deposit was found to consist of calcium oxalate in crystals of large and small octahedrals. Sections of the underlying liver presented no macroscopic abnormality; microscopic specimens taken some three weeks after standing in glycerine formalin showed vacuolation of the hepatic cells beginning in the nucleus, thought by Mr. S. G. Shattock, who kindly examined the microscopic section, not to be merely a post-mortem change; there was also some small cell infiltration of the connective tissue. The vacuoles were not seen anywhere to form microscopic cysts by coalescing. There was therefore a wide difference between this cyst and the multiple cysts of the liver with vacuolation of the hepatic cells described by Eugène Courbis and others in this particular, as also in the appearance and composition of the contents of the cyst.

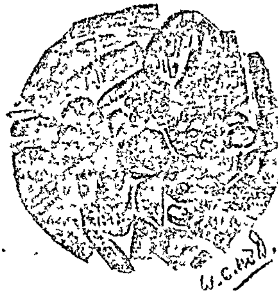

Illustration showing a field of a transverse section of the liver closely underlying the cyst. It shows some of the vacuoles formed in the hepatic cells.

NORTHAMPTON GENERAL INFIRMARY.

A CASE OF ADDISON'S DISEASE WITH ASSOCIATED LEUCODERMA AND TUBERCULOUS PERITONITIS.

(Under the care of Dr. F. BUSZARD.)

THERE are probably several distinct morbid conditions which agree in being characterised by the formation of whitish patches on the skin, though the same name, "leucoderma," is applied to them all. The alterations in pigmentation in Addison's *disease* chiefly take the form of marked increase in depth of colour in certain situations, but occasionally, as in the very interesting case recorded below, patches of paler skin appear. These may reasonably be called cases of leucoderma in spite of the association with Addison's disease. Our knowledge of the mechanism by which disease of the suprarenal capsules may lead to alterations in the pigmentation of the skin is at present very indefinite, but it is not improbable that an increase of our knowledge in this direction may assist us in the pathology of true leucoderma. For the notes of the case we are indebted to Dr. Horace Colman, late assistant house surgeon.

A man, aged 40 years, was admitted into the Northampton General Infirmary on August 20th, 1898 He complained of general weakness of some long standing and of changes in [illegible] anything [illegible] cited from [illegible] onset of his [illegible] He could [illegible] him that might be supposed [illegible] symptoms and anything to do with the onset. The weakness had increased of late and owing to his being too feeble to work he had not been getting sufficient food.

In appearance the patient was a very thin man of about the average height; his weight was only 8 st. 3 lb. He looked extremely ill and was very feeble indeed. The most striking feature was the pigmentation of the skin. Generally the skin presented a dirty-brown "unwashed" appearance which the patient said was of one or two years' standing. On the mucous membrane of his lips were deeply pigmented patches, but there were none inside the mouth, and there was no excessive pigmentation in the axilla or on the nipples or genitals—that is to say, there was no change in the proportion between those parts and the surrounding skin. In contrast to the general darkening of the skin there were patches of pure white. These were situated on the side of the nose, one cheek, and upper lip (the hair in the patches on the upper lip was perfectly white). Patches were also seen on the front of the knees and the abdomen. The palms of the hands were of a fresh, clean, white colour, as were the dorsal surfaces of the last two digits. On the dorsum of each hand there were irregular patches as well. (The patient had been a stableman and groom when able to work, so that there does not seem to be any probability of his occupation having any particular bearing on the state of his hands.) The margins of the various patches were even more deeply pigmented than the surrounding skin, the appearance suggesting that the pigment had been carried out and heaped up peripherally, and the manner in which the patches increased seemed to confirm this suggestion. Physical xamination revealed nothing further except an exceedingly eak pulse, small and rapid. The heart sounds were very int. The temperature occasionally rose to 99° F. at ght, but was subnormal during the day. The urine s alkaline, the specific gravity being 1010; there was albumin or deposit, but on heating phosphates were ecipitated.

While in the infirmary the patient improved for the first days, doubtless owing to good food and complete rest. n, however, the weakness gradually increased and he was bled with diarrhœa that could only be partially checked he use of opium. For the last few days of his life he red from constant and uncontrollable vomiting which nued in spite of rectal feeding. 14 days after admis- he died. During that fortnight a marked increase was d in the size of the white patches. This was very s on his upper lip, where almost the whole of his ache had become perfectly white. The treatment con- at first of a tonic of iron and strychnine, then it was d to stopping the diarrhœa, and just before the vomit- rted he was given suprarenal tabloids but he only took three.

psy.—A post-mortem examination was made by Dr. on the following day. The lungs were found to be except that the right one was completely adherent est wall and to the diaphragm. The heart was very he valves were healthy, and the muscle appeared so ked eye. The whole of the peritoneum was studded tubercles varying in size from that of a pin's head f a hemp-seed. These were also present on the the liver, spleen, bladder, and small intestine, the large intestine or stomach. There was some nt of the retro-peritoneal glands, but there was ulceration of the intestines. The liver, spleen, eas appeared to be healthy. The left kid- ealthy, but the right had several small cold in it. These were unconnected with one without any communication with the pelvis of or the surface. The suprarenal capsules were ely destroyed by tuberculous disease. The left nd almost entirely caseous. The right was not ensively diseased and contained one or two m and apparently healthy tissue. In order ould be no doubt as to the nature of the r. Colman submitted the capsules to Dr. H. D. t. George's Hospital, who very kindly under- ne them. He pronounced them both to be estroyed and infiltrated by fibro-caseous

Dr. COLMAN.—The interest of this case lies tion of leucoderma with the excessive pigmentation of Addison's disease and, as re necropsy, the tuberculous lesions of the per kidney. The leucoderma increased rapidly whil was in the infirmary and seemed undoubtedly t some change in the nutrition and innervation which carried the pigment (previously in ex localised areas and heaped it up all round; the size and shape of the patches could be noticed day. Another point was that the areas normally did not show any increase out of proportion occurring to the skin generally. The small expected in the light of the small and we and the faintness of the heart sounds. The was really astonishing and I much regret that when the post-mortem examination I had no means of careful measurements of the organ, but a heart of of 14 years of age would about represent it. The culous peritonitis gave rise to no symptoms unless i to the general weakness and increased the diarrhœa abscesses in the right kidney were evidently not cau direct spreading from the suprarenal capsule as the healthy tissue between. It is probably impossible to m definite statement of the order of infection but the di was most marked in the capsules and least advance the peritoneum, and in an intermediate stage in the kidney.

About the same time there was in the infirm another case of Addison's disease. This case was fatal but in spite of all my endeavours I was unable gain permission to make a post-mortem examinati The chief point of interest in this case was the long durati and the sudden termination. Three years before admissi the patient began to feel weak and faint at his work and the same time was troubled with causeless vomiting. Th onset was rather sudden, but he knew of nothing to which might be attributed. He had no pain in the back and n diarrhœa. Two years before admission a change in the colour of his skin was noticed which had gradually become darker. He had been unable to work for some weeks, but he walked up to the infirmary and walked upstairs with apparently little fatigue. His skin was of a dusky hue all over and the nipples were very dark. On the palate there was a dark, purplish patch of about the size of a sixpence. The pulse was full and soft. Two days after admission, on rising to go to stool, he fainted and collapsed on to the next bed. Nine days after admission I took some notes on the history. After about half an hour or so he seemed very tired and vomited; though no examination had been made and he lay on his back all the time. He took his tea soon after, but half an hour after that his heart suddenly failed and he died within five minutes of the first alarm.

I am indebted to Dr. Buszard for permission to publish the above case.

CUMBERLAND INFIRMARY.

TWO CASES OF INTUSSUSCEPTION; OPERATION; RECOVERY.

(Under the care of Dr. H. A. LEDIARD.)

THE trend of surgical opinion of recent years as to the treatment of acute intussusception has been very distinctly in the direction of primary laparatomy, that is to say, laparotomy which has not been preceded by ineffectual attempts to reduce the intussuscepted bowel by injection or inflation. This change in treatment is amply supported by statistics. For instance, in the Transactions of the Clinical Society of London[1] Mr. A. E. Barker records 15 cases in which he did laparotomy and nine of these recovered. If only the large intestine be involved, as in the first case recorded below, the symptoms are less acute, but in any case the earlier the operation is performed the greater the chance of success, and the operation should be carried out as rapidly as possible. Dr. Lediard is to be congratulated on his satisfactory results. For the notes of these interesting cases we are indebted to Dr. Cairns, late house surgeon.

CASE 1.—A boy, aged two years and five months, was admitted into the Cumberland Infirmary on the foren Nov. 1st, 1899. The illness commenced with sl on Oct 29th On the 30th the vomiting was more severe and was accompanied by diarrhœa and the passage of bloody mucus As the child became steadily worse and was evidently suffering great pain Dr J W Crerar of Maryport was called in on the evening of the 31st He diagnosed intussusception and, all attempts at reduction failing, advised immediate operation On admission the boy was well under the influence of opium and his general condition was remarkably good considering that this was the fourth day of the illness The temperature was normal, the pulse was 110, and the respirations were 30 per minute On abdominal examination an elongated mass, apparently about five inches long, could be felt lying obliquely in the left iliac fossa and extending upwards well above the brim of the pelvis The liver dulness was diminished, and there was some general abdominal distension, but no evidence of fluid was present On rectal examination the lower end of the mass could just be felt above the brim of the pelvis Attempts at reduction by enemata, inflation, &c, all proved unsuccessful, and at 4 30 P M on Nov 1st (i e, almost exactly four days from the appearance of the first symptoms), laparotomy was performed by Dr Lediard An incision about four inches long was made over the tumour and the peritoneum was opened with the usual precautions, the intussusception was readily found and proved to be colon into colon, forming a large elongated mass nearly seven inches long The bowel was extremely congested, but not gangrenous, and the intussusception was reduced only by the exertion of a considerable amount of force The peritoneum and abdominal wall were then rapidly stitched up by interrupted fishing gut sutures and the child was put back to bed the whole operation having occupied less than 20 minutes He passed a restless night and became quite delirious on the following day, the temperature reaching 103 2°F. at 8 P M, but after several doses of a mixture containing sulphate of quinine, tincture of digitalis, and solution of hydrochlorate of morphine, he became much quieter and on the following day his temperature had fallen to normal Flatus was passed several times during the second day after the operation, and on the third day the bowels were moved freely after an enema of soap and water From this point recovery was practically uninterrupted and after removal of the stitches on the ninth day no further trouble was experienced

---

[1] Vol. xxxi., p. 65.

CASE 2 —A male infant, aged six months, was admitted into the Cumberland Infirmary on the afternoon of May 18th The illness commenced on the night of the 16th with vomiting and diarrhœa, accompanied later by the passage of blood stained mucus Dr D S Doughty of Dalston, Cumberland, saw the patient on the afternoon of the 17th and diagnosed intussusception, but was able to reduce it by injection of air and fluid All the symptoms then disappeared and the child became perfectly quiet, but the vomiting, &c, recommenced on the morning of the 18th, and Dr Doughty, after again seeing the child, advised immediate operation. On admission the child looked very ill and cried almost continuously The vomiting, diarrhœa, &c persisted, and on examining the abdomen a large sausage-shaped mass could be felt stretching transversely across just above the umbilicus, another mass could be felt low down on the left side just above the pelvic brim, giving one the impression of two distinct intussusceptions, but nothing could be detected per rectum As the condition had recurred after previous reduction by inflation the abdomen was immediately opened by Dr Lediard and a very large intussusception was found It extended from the left iliac region upwards and backwards towards the splenic flexure and then transversely across to the right side of the abdomen, being at least 10 inches long Reduction was effected by careful and prolonged traction, and the last portion of bowel to emerge was the cæcum with the vermiform appendix —i e, practically the whole of the large intestine had been involved The abdominal incision was then rapidly stitched up by interrupted sutures of fishing gut, and the child was back in bed within 20 minutes of the commencement of the operation Vomiting continued intermittently for a few days after the operation but disappeared on the substitution of peptonised milk for the mother's milk, and the further progress of the case was uneventful The bowels were moved naturally on the day following the operation, the stitches were removed on the eighth day, and the child was discharged cured on June 3rd less than three weeks from the date of the operation

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Discussion on the Mastoid Operation for the Cure of Chronic Purulent Otorrhœa

A MEETING of this society was held on Feb 13th, Mr. THOMAS BRYANT, the President, being in the chair

Mr SEYMOUR LUCAS, in resuming the adjourned discussion on the Mastoid Operation for the Cure of Chronic Purulent Otorrhœa, admitted that the operation suggested would no doubt lessen the time of suppuration and prevent recurrence. In the plan suggested after the first operation was done and healed it was necessary to again open up the wound and repeat the operation This seemed to him the only defect of the operation under consideration Even a third operation might be necessary to remove the piece of gold leaf. It would be a great advantage if it could be done all at once It was not so easy to get patients to submit to two operations for one result In times gone by he had been struck with the pain suffered by children with large burns who had to supply grafts for their healing In 1884 he had suggested the use of preputial skin, of which there was a superfluous amount Some one had suggested that frogs' skin would serve Might not this be utilised in the present operation? Turning to the question as to what cases it was desirable to interfere with, each case must be treated on its own merits In cases of doubt it was a good rule to operate The selection of cases was, no doubt, a very difficult matter He referred to the case of a child, aged nine years, who had had otorrhœa for three months. On admission he was suffering from headache, sickness, constipation, nausea, and vomiting, and he was drowsy and stupid There were slight ptosis on the right side and optic neuritis. The symptoms were thought to be due to cerebral abscess from otorrhœa But eventually he died and the child was found to be suffering from meningeal and universal tuberculosis

Dr. WILLIAM MILLIGAN remarked that the treatment of chronic suppuration of the middle ear was a subject of very great importance As to the indications for operation those cases attended by severe pain, by facial paralysis, and by obvious external indications of mastoid disease called for operation In some cases also in which objective symptoms were not present, and whenever there was reason to believe that deep-seated suppuration was going on—though these cases were sometimes difficult to decide—operation was called for Chronic suppurative otorrhœa was a very grave condition It might be followed at any moment by acute intra cranial symptoms and death Moreover, otorrhœa was always attended by a lowering of the general health His own idea was that as a general rule surgical interference was delayed too long. It might be done with propriety in the subacute stage as soon as the acute symptoms had subsided Turning to the kind of operation, Mr. Ballance's technique constituted a distinct advance The time of after-treatment was thereby much lessened In an ordinary Stacke's operation it took four months for complete cuticularisation and here it could be completed in three or four weeks He did not quite understand Mr Ballance's disposition of the cutaneous flap He had tried grafts on the inner wall of the middle ear, over the promontory, and such cases healed more quickly

Mr ARTHUR BARKER entirely concurred with the readers of the various opening papers As regards the selection of cases the three indications given in the summary formed the limit beyond which they could not with safety go He especially agreed with the statement that experience was a better guide than any hard and fast rules This led him to the conclusion that this department of surgery was in one sense a legitimate speciality But, on the other hand, he did not believe that Mr. Ballance would have been led to this operation had it not been for his general surgical training He was not sure if the covering with gold leaf was absolutely essential Lately he had found several folds of gauze answer this purpose and it could be left *in situ* for some days

Mr H. SECKER WALKER remarked that he always made a very free incision at the start and then completely removed the pillar of bone running between the antrum and the attic. It was only in this way that the operator could see what was the real state of the tympanum, and for this purpose he used a strong searchlight. He would like to ask if it was necessary to keep the ear cartilage in the flap that was turned up. He thought it best to dissect it out. He had until lately used chisels and mallet, but the burr was a great advantage.

Dr. DUNDAS GRANT remarked that the indications for the operation required careful consideration. Pain and vertigo were very strong indications for operation unless these could be otherwise explained by visible removable causes. Sometimes vertigo ceased after the removal of a granulation which was pressing on the stapes. Caries was also a decided indication unless it was limited to the outer wall attic, as also was the occurrence of facial paralysis or of nerve-deafness. And there was one more—general ill-health—which was a reason for operating which was not realised as much as it ought to be. Even a trace of albuminuria was not a contra-indication, rather the reverse. The degree of hearing power which the patient retained was an important factor. If the patient could hear a whisper at three feet distance the tympanic apparatus was still of some value. If the hearing power were below that an operation might be more readily agreed to. Persistent suppuration in spite of intra-meatal treatment was one of the strongest indications for operation. As to the temperament of the surgeon, which one of the earlier speakers had alluded to, perhaps aurists had been of a too conservative temperament and prided themselves on curing their cases without operation. He had seen several unfortunate cases of sudden supervention of meningitis and the possibility of this was always before the patient. Consequently the responsibility of deciding against the operation was greater than deciding for it. He was glad that the suggestions made by Mr. Ballance enabled them to cope with cases more readily.

Dr. WILLIAM HILL wished to ask Mr. Ballance what proportion of the cases operated on were likely to fail and whether this operation could be applied in all conditions of the hearing.

Mr. C. A. BALLANCE in reply, felt sure that his methods could be gradually improved. In all his cases the operations were done because life was in danger and because there was nothing else to be done. He did not, therefore, hesitate to give chloroform twice. He had considered preputial skin and the skin of the frog, but these did not recommend themselves to him. He had not yet found anything as satisfactory as the epithelium of the patient. He had not got as good results without gold-leaf as with it. The dissection out of the cartilage of the ear from the flap, as suggested by Mr. Walker, would certainly, he thought, be a gain and he would gladly adopt it. The cavity must, as Mr. Walker had said, be thoroughly opened up. His answer to the question whether he would operate on a patient whose hearing was good was in the negative.

Sir WILLIAM DALBY wished to add his testimony to the completeness of Mr. Ballance's operation. It had been truly said that this operation was not as easy as it seemed, requiring great delicacy of touch as well as very accurate knowledge of anatomical relations. It might be well to remember that Mr. Ballance had been operating on these cases for 15 years before he was satisfied with the details in his methods. In his portion of the paper Sir William Dalby had attempted to formulate the conditions and symptoms which led to the selection of cases for operation, and it was noticeable that in two or three of Mr. Ballance's cases in which Sir William Dalby had advised the operation he had 20 and 17 years before seen these cases and given an opinion as to the possible dangers in the future. In one of these he had opened the antrum for urgent symptoms. This was at a period when their knowledge did not permit of the operation now under discussion. There were also many cases in the past in which he had opened the mastoid cells and saved life by so doing, but which would have been far better treated if they had then known that an operation like Mr. Ballance's was possible and would once and for ever protect against risk of septicæmia and other dangers.

Mr. A. E. CUMBERBATCH remarked on the delicacy and skill required for the operation. It was not one which could be taken up lightly. That was why in his teaching he seemed more conservative than in actual practice, for so much depended on the operator.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Feb. 12th, Mr. G. R. TURNER, Vice-President, being in the chair.

Mr. F. C. WALLIS exhibited a case of Resection of the Small Intestines in a Boy, aged seven years. About two years previously he had been under treatment for tuberculous peritonitis in a London hospital, and about a year after that acute intestinal obstruction had occurred. For this the abdomen was opened and a piece of small intestine above the obstruction was sewn to the abdominal walls, opened, and a fæcal fistula resulted. The patient then went to St. Monica's home, at which place the operation of enterectomy was performed by Mr. Wallis on Dec. 1st, 1899. Five inches of small intestine were removed, and the cut ends were joined by interrupted sutures. The boy made a very satisfactory recovery in spite of the septic conditions of the skin which for a considerable area round the original wound was red, inflamed, and discharging pus, on account of the irritation and partial digestion caused by the contents of the small intestine constantly flowing over it. The pieces of resected intestine were shown.

Mr. FRANCIS JAFFREY showed a case of Urticaria Pigmentosa occurring in a male child aged 15 months. The eruption was universal and consisted of wheal-like patches, each lasting from a day to a day and a half, leaving a stain on disappearing. The patches were slightly raised and varied in size from a split pea to a shilling-piece. The eruption had been going on for about 10 months, as it first appeared when the child was five months old. Mr. Jaffrey remarked on the rarity of the condition and said that most of the recorded cases were in boys.—In reply to Dr. W. EWART Mr. Jaffrey said that the patient had not had any arsenic and that there was no alteration in the spleen.

Dr. C. W. CHAPMAN exhibited a case of Cyanosis from Birth due probably to congenital cardiac disease, though no cardiac murmur was present. The symptoms consisted of severe breathlessness and convulsive attacks in which consciousness was lost and the patient sometimes bit her tongue. There was slight clubbing of the fingers and toes. The cardiac defect probably consisted of a transposition of the great vessels and possibly the patent foramen ovale. Both the arteries and the veins of the fundi oculorum when examined by Mr. Adams Frost were much dilated.—Dr. EWART agreed with the diagnosis and suggested that possibly there was a very large opening, too large to produce a murmur. The valves were probably normal.—Sir HUGH BEEVOR commented on the very marked pulsation in the second left interspace although the dulness was diminished in that situation. There was evidently a dilated right ventricle and possibly the aorta arose on the left-hand side of the heart.

Sir HUGH BEEVOR, Bart., showed a case of Cardiac Disease with Pulsus Bisferiens. The patient was a male, aged 23 years, who had been subject to dyspnœa on exertion since an attack of chorea at the age of 11 years. Cardiac and arterial symptoms of aortic regurgitation and stenosis were present. Pulse tracings which were shown adduced confirmatory evidence. The symptoms pointed to the existence of a contracted aortic orifice but not to any great degree of narrowing. The effects of mitral incompetence had been apparent from time to time during the last two years, for the patient had had anasarca and hæmoptysis and the liver now extended just beyond the margin of the ribs.

Mr. A. J. BARKER exhibited a patient, aged four years, who suffered from Congenital Dislocation of the Hip. Nothing was noticed wrong with the child until she began to walk, and then she "waddled" in the characteristic manner. A marked feature about this case was the twisting forwards of the head of the femur. It was the rule for it to be twisted forwards in congenital dislocation, and this was well shown in the skiagram which was exhibited. As regards the prospects of operation in such cases, out of 360 cases collected by Lorenz it was only in a very small proportion that this observer had been able to bring the head into relation with the acetabulum. This was proved by the last 135 cases which were skiagraphed.—Mr. F. C. WALLIS remarked that the advantages to be derived from operation in such cases appeared to be extremely limited, and he referred to two cases of operation which were exhibited together at the Clinical Society of London, and at the same time to the case of a girl, aged

17 years, who had not been operated upon. This comparison was not in favour of operation.—Mr. J. LYNN THOMAS referred to a case upon which he had operated two years ago for double congenital dislocation. The patient was kept in a double Thomas's splint for nine months. The case did very well, but the head of the bone was on the dorsum ilii a little higher than before. Nevertheless the "waddling" had disappeared so far and this was a great advantage.—Mr. BARKER, in reply, did not at all wish to advocate the operations which had hitherto been done, for the results were not at all encouraging. There was in his experience not much gained by operation.

Dr. EWART exhibited an Automatic Respiratory Jacket or Waistcoat for applying continuous pressure to the chest in cases of emphysema. It was intended to be worn night and day. It was provided at the sides and over the shoulders with elastic, the tension of which could be adjusted. A boy suffering from emphysema was also exhibited. Dr. Ewart remarked that the boy's chest measurement had decreased while wearing the jacket for six weeks, and his symptoms had improved.

Mr. E. H. WILLOCK also demonstrated an apparatus designed for the same purpose—namely, the relief of emphysema. It was not like Dr. Ewart's for applying continuous pressure but was intended for intermittent use. The hands were raised and the jacket was relaxed, and as the hands were brought down the chest was compressed by an arrangement of pulleys passed up over a fixed pulley above the head. In treating emphysema with this apparatus expectoration at first was increased and then after a day or two it diminished and the patients improved in other respects. The same apparatus could also be used to teach respiratory exercises to phthisical patients.

Mr. W. H. BATTLE exhibited a case of Tumour of the Femur in a man, aged 29 years. The femur was two inches shorter in length on that side. There was a well marked history of syphilis. Regarding the diagnosis he had considered several possibilities, but had come to the conclusion that it was a case of osteitis deformans involving only one bone. He had only been able to find a record of one similar case, one that was recorded by Mr. A. A. Bowlby in the Transactions of the Pathological Society of London.

Dr. W. J. HADLEY exhibited two rare cases of Rheumatism. The first was a case of osteo-arthritis in a female child, aged eight years. During the past three years she had had five attacks of rheumatism. The first three were ordinary polyarticular rheumatism, which cleared up completely, but the fourth and fifth had left some deformity in the joints. The present attack started in April, 1899, and she was now completely crippled. There was considerable deformity and enlargement of most of the joints which skiagrams showed in the larger joints to be due to increase of the soft tissues; no alteration in the bones was visible. The right hip was fixed and the neck was stiff. There was a systolic bruit at the base which was tending to become less marked and was probably of hæmic origin. The spleen was slightly enlarged. Anti rheumatic medicines had proved useless. Massage and daily sweating of the joints had given fairly satisfactory results. There had been occasional slight elevations of temperature. The second case was that of a female child, aged nine years, who had had chorea three years before. There was no history of rheumatism or of joint affection at any time. The present illness began a week before admission to hospital with pains in the limbs, headache, and two days before admission severe pain in the right foot. There was no definite arthritis at any time. On admission there was well-marked mitral regurgitation with cardiac hypertrophy; the spleen was enlarged, firm, but not tender. After three days of irregular pyrexia there was a sudden rise, accompanied by dizziness, faintness, and vomiting (probably of embolic origin). Ten days later a similar attack, though without pyrexia, was attended by pain in the lumbar region. A presystolic mitral bruit and a systolic aortic murmur also appeared. Later the occurrence of sudden pain in the left arm, with tenderness and other symptoms, pointed to embolism of the brachial artery, and the radial artery had since been pulseless. The first case was interesting by reason of its rarity. It was a typical case of rheumatic arthritis occurring in a child and tallied with the cases reported by Dr. Still. The interest of the second case lay in the occurrence of the emboli which had arisen in the course of endocarditis (certainly of rheumatic origin) in a child.

Mr. J. LYNN THOMAS exhibited a Tourniquet which he had designed for compression of the femoral and other arteries. It consisted of a large pair of forceps somewhat resembling those of Doyen. It was necessary to make a small opening in the skin so as to introduce one blade of the instrument beneath the artery unless it was applied to an amputation flap. The apparatus enabled the operator to dispense with one assistant less and was far more aseptic than the ordinary rubber tourniquet. Mr. Thomas had used it for amputation of the leg, thigh, arm, and penis. Another advantage was that it did not give rise to vasomotor paralysis as did the ordinary tourniquet.

Mr. MCADAM ECCLES exhibited two cases illustrating Variations in Inguinal Hernia due to Abnormal Descent of the Testis. One man, aged 23 years, exhibited interstitial hernia. He had both testes only partially descended, the right being in the canal and the left just appearing at the site of the deep abdominal ring. The hernial sac in his case was probably between the aponeurosis of the external oblique and the muscular fibres of the internal oblique muscles. It was almost certain that the abnormal descent of the testis was a factor in the production of the interstitial sac, but that it was not the only one in all such cases was evidenced by interstitial herniæ occurring in females. Here and in others in the male sex, the smallness or absence of the aperture known as the superficial abdominal ring might play a considerable part in causing the hernial sac to pass in the plane of least resistance. The second case was one of cruro scrotal hernia in which the sac, following the course of an ill-developed testis, had missed the entrance into the scrotum proper and had distended the skin forming the junction of the thigh and the scrotum. The right testis was present in the perineum and was small and tender. The covering of the sac was normal skin and did not contain any dartos tissue. In both cases the scrotum was developed, though in the first and last its right half was undistended by the presence of a testis in it, while in the second case both sides were thus wanting in distension.—Mr. W. H. BATTLE wished to know whether they ought to regard cruro-scrotal hernia as a new variety. He thought that the hernia in one of these cases was very probably associated with injury.—Mr. A. J. BARKER had recently operated on a somewhat similar case occurring in a woman. There was an inguinal hernia and an interstitial one on the same side, and consequently the testicle could not be regarded as essential to the production of the condition.—Mr. G. R TURNER referred to a case of Undescended Testis and Hernia which he had recently operated on, in which he found two distinct sacs. One sac was connected with a congenital hernia and the other went right up into the peritoneum with a bifid neck.—Mr. MCADAM ECCLES, in reply, said that he still regarded the case as a true cruro-scrotal hernia, but he did not wish to refer to the condition as a new form of hernia.

Dr. S. MULLICK exhibited a case of Dextro cardia occurring in a male patient aged 22 years. The patient had come complaining of pain, palpitation, dyspnœa, giddiness, and faintness. The pain was situated under the right mammary region and varied in its character, resembling dyspepsia in some respects. There was nothing in the previous or family history of importance, excepting that one day in August, when ascending a ladder after dinner, he was suddenly seized with severe palpitation, after which he was laid up for some days. The apex beat was on the right side of the chest in the sixth interspace and the cardiac impulse could be seen in the fourth and fifth interspaces. The præcordial dulness extended 11½ centimetres to the right of the mid-sternal line. There were no murmurs.

Dr. E CAUTLEY showed the Heart of a boy, aged 14 years, whom he brought before the last clinical meeting of the society in November[1] as a case of congenital heart disease, probably aortic. The boy was very small for his age and the physical signs were consistent with the diagnosis of aortic stenosis, but the diagnosis was not unanimously accepted at the time, among other suggestions as to the nature of the lesion being a patent ductus arteriosus or a more immediate communication between the aorta and the pulmonary artery. The boy died suddenly eight days afterwards. His heart weighed five and a half ounces and was evidently hypertrophied. The aortic valves were very much thickened, rigid, and adherent at their edges with the exception of a small, irregular, slit-like orifice between two of the valves. No other abnormality was present. The diagnosis of aortic stenosis was therefore correct though the congenital origin of the affection could not be proved.

---

[1] THE LANCET, Nov. 18th, 1899, p. 1363.

CLINICAL SOCIETY OF LONDON.

Cases of Hæmo-pneumothorax.—Perforated Duodenal Ulcer.—Stricture of the Small Intestine following Strangulated Hernia.

A MEETING of this society was held on Feb. 9th, Sir R. DOUGLAS POWELL, the President, being in the chair.

Dr. H. D. ROLLESTON made a communication on a fatal case of Hæmo-pneumothorax of unexplained origin. The patient was a male, aged 21 years, whose past history showed nothing but dyspepsia. After some diarrhœa and abdominal pain, lasting two days, he was suddenly seized with agonising pain in the right hypochondrium, radiating to the umbilicus and right shoulder. On admission, 24 hours later, to St. George's Hospital he appeared to be moribund, but subsequently he rallied and next day had signs of pneumothorax on the right side with considerable displacement of the heart. Some doubt existed as to whether the collection of gas was above or below the diaphragm. Paracentesis of the right side of the chest brought out blood and some air under considerable pressure. Death occurred from exhaustion and bronchitis eight days after the onset of acute pain. At the necropsy the right pleura contained 60 ounces of blood. The thoracic wall was opened under water and no air was found in the right pleura. Except for collapse the lung was healthy. Microscopically there was no evidence of tubercle or pleurisy. There were no signs of hæmophilia, scurvy, cirrhosis of the liver, aneurysm, or traumatism. No cause for the blood or for the gas in the pleura was forthcoming.—Dr. NEWTON PITT narrated the history of a case of Hæmo-pneumothorax which had been under his care which was apparently due to the rupture of an emphysematous bulla. The patient was tapped during life and eight fluid pints of blood were removed. After death both air and fluid blood were found in the pleura. Dr. Pitt discussed the various causes of hæmothorax. Apart from traumatism the cause of this condition was always some lesion of the lung, such as tubercle, caseous pneumonia, pulmonary apoplexy, gangrene, or abscess of the lung. Blumenthal maintained that hæmothorax was occasionally a primary condition, but that seemed doubtful. Some tuberculous lesion was the commonest cause, but no evidence of this could be found in the case under consideration.—Dr. HINGSTON FOX referred to the case of a man, aged 44 years, who was in very robust health until he was suddenly taken with symptoms resembling an attack of pleurisy. There were pyrexia, pain in the chest, and signs of pleuritic effusion. He was tapped and 15 ounces of dark blood came away, but the tube got blocked. Three days later there were signs of air and of fluid in the chest and the patient was again tapped. This time 45 ounces were removed and the aspirator tube discharged bubbles of air under water. After this the patient got gradually well. A tuberculous lesion was suspected and he was sent away for a voyage, but he remained quite well and had been in robust health ever since. It was worthy of note that this patient was employed in a very badly ventilated office in the city which was built over made ground which had subsided, sewer air gaining access to the building. Three other employés in the same office broke down with tuberculous mischief in the lungs.—Sir DYCE DUCKWORTH thought that in the majority of these cases the sequence of events was first a rupture of lung tissue followed by ordinary pneumothorax, this being followed by hæmorrhage, and behind the whole was tuberculosis.—Dr. SAMUEL WEST recalled a curious case of Pyopneumothorax. The patient was operated on and the pus was removed, but shortly afterwards hæmorrhage took place in both directions, the patient being attacked with hæmoptysis and hæmorrhage into the pleura. At the necropsy he was found to have a tuberculous cavity in which an aneurysm had ruptured, giving rise to copious hæmorrhage in both directions.—Dr. PERCY KIDD asked whether the bacillus capsulatus aërogenes could be quite excluded. He understood that there was no tuberculosis in either Dr. Rolleston's or Dr. Pitt's case.—The PRESIDENT said he would like the question of the presence of air cleared up; and another question was, Did the blood precede the air or did the pneumothorax precede the hæmorrhage? An interesting point in Dr. Newton Pitt's case was the enormous amount of hæmorrhage which had taken place. He once made experiments by injecting fluid into the pleura at post-mortem examinations and he never succeeded in injecting more than six or seven pints at most. He said it was curious that the blood should remain liquid in the presence of air.—Dr. H. D. ROLLESTON, in his reply, said that in his patient the illness was initiated by diarrhœa and abdominal pain, symptoms which might point to a toxic condition. He had made the most careful search, but could not find any evidence of tubercle in the lung or pleura. If the air had arisen from the bacillus capsulatus aërogenes there would probably have been more air after death rather than less, for the microbe would go on increasing rather than dying out after death.—Dr. NEWTON PITT, in his reply, said that the only preceding symptoms in his case were sore-throat and diarrhœa for three days. He had expected to find tubercle, but had failed to do so. Alluding to the amount of effusion present, he referred to a case of pleuritic effusion in which seven pints had been removed, and he believed as much as 11 and 12 pints had been recorded. As regards the order of appearance of the air and the blood, even when the case was first seen air was present, but it was impossible to say precisely which had been primary.

Dr. J. J. PERKINS and Mr. C. S. WALLACE made a communication on a case of Perforating Duodenal Ulcer; Operation; Recovery. The patient, a male, aged 52 years, was admitted to St. Thomas's Hospital complaining of epigastric pain of three days' duration with a violent exacerbation six hours before. There had been no vomiting. The abdomen was tense, rigid, almost motionless, with complete absence of liver dulness in the nipple line. Ten hours after the onset of acute pain the abdomen was opened through the right rectus, the age and sex of the patient, the history, and the absence of liver dulness making it probable that a duodenal ulcer had perforated. A perforation was discovered at the junction of the first and second parts of the duodenum; the edges were clean cut and showed no sign of induration. The intestines showed some points of injection, but there were no very evident signs of peritonitis. The perforation was closed with two rows of sutures and the abdomen cleaned after evisceration and flushing with sterilised water. The abdominal opening was closed with silkworm-gut sutures and by a row of buried sutures. A gauze wick was left in passing down to the seat of the ulcer without further drainage. Convalescence was uneventful; the plug was removed on the second day, the bowels were opened by enema on the third day, and milk was first given by the mouth on the tenth day. Operation on these cases was favoured by the site of the perforating ulcer, which in 29 out of 37 reported cases was on the anterior wall. The condition of the abdomen when seen was that of early peritonitis, rigidity, contraction, and loss of movement. Paroxysmal exacerbations of pain due to peristalsis increased the resemblance to colic. The complete absence of the liver dulness internal to the nipple line was to be taken as a guide. In locating the perforation to the duodenum the previous history of the patient was an aid in perhaps half the cases, though perforation in many cases occurred without the slightest previous warning. The site of the pain caused by the perforation at its onset was of great help though occasionally misleading. From statistics it was clear that duodenal ulcer could hardly be diagnosed from gastric ulcer. The resulting peritonitis was sometimes diffuse from the first, but often the great omentum shielded the mass of the intestines and directed the extravasation to the pelvis. The right lobe of the liver on its upper aspect and the parts round the duodenum were especial sites of the inflammation in these cases and special care should be taken in cleansing these regions. The whole abdomen, however, should be irrigated, the intestines being turned out and themselves flushed. Drainage was not required, but a gauze wick should be left in the abdominal wound running down to the site of the ulcer. The collapse which was a marked feature of these perforations high up should be met by saline infusion and operation proceeded with as quickly as possible.—Mr. W. H. BATTLE congratulated Dr. Perkins and Mr. Wallace on the result. He had occasion some time since to look up the statistics of the operations for ruptured duodenal ulcer and was surprised to find how very few recoveries were known. The cases which he had seen were admitted for general septic peritonitis and there was no means of finding out before the operation where the origin of the disease was The presence or absence of vomiting was not a help Only recently in a case of perforated ulcer of the stomach situated not far from the pylorus there was marked vomiting He considered that the operator in Dr Perkins's case was lucky to be able to operate so soon after the commencement of symptoms —Mr ARTHUR BARKER wished to allude to the plan of irrigation and removal of the intestines adopted by Mr Wallace He and many other surgeons did not at all agree with this course and because the case was successful he felt it all the more incumbent on him to protest against the procedure This manipulation of the intestines was in most cases attended by considerable shock It was much better to soak up the effused fluid—which was not always widely effused—with gauze and to trust to the peritoneum to dispose of the rest Even when extravasation was widely effused it was possible to clear out both flanks and other parts of the peritoneum by straps of antiseptic gauze He wished to protest against both the evisceration and the irrigation Either alone was dangerous The peritoneum had a marvellous power of dealing with septic matter in moderate quantity —Mr PEARCE GOULD would like to know whether the previous speaker had been right in referring to the contents of the stomach as septic matter It was irritating from its acid condition no doubt and the injury of the peritoneum might lead to septic absorption —Dr F J POYNTON thought that duodenal ulcer was more frequent than was generally believed, or else perhaps it was on the increase During two years' necropsies at St Mary s Hospital he had met with eight fatal cases and had seen several others in the hospital wards Of these eight six were male and two were female their ages ranging from 28 to 55 years One of these had no symptoms at all during life and a second was admitted for cardiac failure and died from melæna In four acute perforation occurred and two of these were operated on Turning to their pathological aspect all the ulcers were chronic with raised thickened edges and had formed considerable adhesions The leading symptoms were prolonged dyspepsia and abdominal pain sometimes very severe, extending in some cases for from five to ten years The great severity of the pain was the chief point In two of the cases the pain only occurred at night as in a special form of dyspepsia and they were free from pain during the day The difficulty of diagnosis and the chronic nature of the ulcers, together with the uselessness of medical treatment were some of the lessons derived from these cases In six of the cases the duodenal ulcer was associated with chronic renal disease, but probably there was a common cause underlying both The prevalence in the male sex constituted a hint to surgeons as to diagnosis, and the presence of firm adhesions in all the cases was also a hint so that they might avoid breaking down protective adhesions —Mr J CHARTERS SYMONDS agreed with Mr Barker that evisceration added to the risk of an operation and it seemed to him an unnecessary proceeding Not to flush the abdomen at all in every case was perhaps carrying things to the other extreme Probably flushing and then mopping with gauze without removing the intestines was the best The various cases must be dealt with differently according to the extent of the extravasation He referred to a case in which he had divided the duodenum for the relief of distension and distress —Dr J J PERKINS in his reply, regretted the absence of Mr Wallace in South Africa, as he would have been able to refer to the surgical aspect He remarked that it was the absence of adhesions which lead to perforation At least, they were wanting in most of the recorded cases of perforating duodenal ulcer as compared with non perforating ones

Mr F H KELLOCK read a paper on a case of Stricture of the Small Intestine following Strangulated Hernia The patient a youth aged 16 years was admitted to the Middlesex Hospital for strangulated left inguinal hernia Two years previously he had been operated on at the West London Hospital for hydrocele in connexion with an imperfectly descended testis on this side He had had a hernia for some time but had always been able to reduce it easily ; he had not worn a truss He had strained himself on the morning of admission the hernia came down and he could not reduce it On admission he was a good deal collapsed and was vomiting the swelling in the left inguinal region was as large as an orange At the operation there was no fluid in the sac which contained a piece of discoloured omentum and about four and a half inches of small intestine, the latter was very dark in colour, but still retained a shiny appearance and after the constriction had been divided and a little more intestine drawn down the colour improved a little The intestine was therefore returned to the abdomen and then the testicle was found lying internal to and behind the hernial sac The testicle and tunica vaginalis were removed and the operation was completed by closing the inguinal canal and skin by sutures For three weeks the patient did well Then he began to suffer from slight pain in the abdomen, some vomiting, and occasionally slight distension of the abdomen On one occasion he had a rigor lasting 15 minutes, when the temperature rose to 102 2° F, but with this exception the temperature was normal throughout By the use of medicines and enemata these symptoms were relieved and the patient was sent to a convalescent home five and a half weeks after the operation The bowels were then acting regularly and he was free from pain During his stay of three weeks at the home he had occasional pain in the abdomen, constipation, vomiting, and some distension of the abdomen, and these symptoms continued more or less till his re admission to the hospital six weeks after his discharge For a few days he improved under treatment but then the symptoms returned, so the abdomen was opened in the middle line below the umbilicus A coil of small intestine was found in the right iliac fossa, which was considerably constricted, the gut above it was hypertrophied and dilated, that below of about normal size, a piece of omentum containing rather large vessels was attached to the front of the coil This piece of omentum was ligatured and divided and a lateral anastomosis made by Halstead s method uniting the intestine above and below the constricted portion For two or three days the patient made fair progress but then the abdomen became distended and tender showing evident signs of general peritonitis, vomiting recommenced and the general condition became very bad The wound was re opened and a drainage tube was inserted leading down to the seat of operation Death occurred about 15 hours subsequently At the post mortem examination general peritonitis was found, the anastomosis was found to be firm and watertight with a good opening between the portions of bowel united There was gangrene and perforation of the coil of small intestine, which had been put out of action by the anastomosis, and the mesentery attached to it was hard and puckered In this portion a stricture was found extending about half an inch in the long axis of the bowel and almost completely obstructing the lumen Attention was called to the rarity of stricture of the small intestine to a degree calling for operative treatment as a result of strangulated hernia The association of inguinal hernia and imperfectly descended testicle was common, but in this case the hernia was not of the congenital variety as the tunica vaginalis was separate from the sac of the hernia The bowel was returned to the abdomen at the first operation rather than resected, as it was thought it would recover, more especially in a patient of this age At the second operation the chief interest was in the piece of omentum which was adherent to the bowel, it was noticed at the time that this contained large vessels but the importance of this fact was not recognised till later What had apparently occurred was that at the time of the strangulation this mesentery had been severely constricted and after the return of the bowel it had become adherent to the omentum, and, nourished in this way and not by means of its mesentery the division of this piece of omentum had cut off the blood supply of the coil of intestine, which had therefore become gangrenous and perforated, setting up a general and fatal peritonitis It was disappointing that such an unlooked for occurrence should prove fatal in a case which otherwise promised so favourably —Mr W H BATTLE considered that stricture of the small intestine due to inflammation of the wall or its consequences was a rare condition He had only found it in three cases of obstruction on which he had operated In the first case, that of a boy the symptoms were chronic, the local state was inflammation of the bowel wall secondary to a caseating gland in the mesentery Lateral anastomosis was performed and gave good result In the second case that of a youth who had been under his care for a sinus remaining after some operation about the appendix two years earlier, the symptoms were acute and depended on cicatricial contraction of the ileum near the ileo cæcal valve Here the operation of enteroplasty was unsuccessful The third case was that of a man about 60 years of age, with acute symptoms of obstruction. He had a reducible inguinal hernia of several years' standing. At the operation a cicatricial contraction of the small intestine with a twist in the normal gut was found. It was considered advisable to restore the channel by reduction of the volvulus rather than by doing an anastomosis. His condition was bad and it was feared that he might not be able to stand the prolonged operation. Recovery was satisfactory, but on the return of symptoms some months later the bowel was short-circuited with much relief. Almost a month ago he (Mr. Battle) had operated on a large irreducible femoral hernia in which there was marked cicatricial contraction of the small intestine which had formerly been exposed to nipping by a truss and was adherent to the bottom of the sac.—Mr. CHARTERS J. SYMONDS remarked that Mr. Kellock had attributed the fatality of his case to failure of the blood-supply and he would like to know whether the gangrene was limited to the part above the stricture.—Mr. KELLOCK, in reply, stated that this was so; nearly the entire loop of bowel was dark and gangrenous. The blood-supply of this part of the bowel had been derived from the omentum, the vessels of which were enlarged. This was one of the chief points of interest in the case.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Case.—Fibrinous Bronchitis.—The Pathology and Treatment of Pneumonia.

THE eighth ordinary meeting of the session was held on Jan. 25th, Mr. EDGAR BROWNE, the President, being in the chair.

Dr. T. R. BRADSHAW showed a man, aged 24 years, with Extreme Atrophy of the Right Trapezius, Biceps, and Brachialis Anticus. The wasting had come on gradually and its distribution suggested the commencement of the facio-scapulo-humeral form of idiopathic muscular atrophy, but it was possible that it was due to over-use of the affected muscles.

Dr. MAX LOEWENTHAL read notes of a case of Fibrinous Bronchitis.

Dr. NATHAN RAW read a paper on the Pathology and Treatment of Pneumonia, based on an observation of 1047 cases occurring during a period of 12 years. The general death-rate of the whole of the cases was 23·4 per cent. During the last two and a half years 317 cases of pneumonia had been admitted into Mill-road Infirmary (including, of course, all forms of pneumonia and those dying shortly after admission), with a total death-rate of 34 per cent. With respect to the pathology of the disease there could be no doubt that it was caused by a specific micro-organism, the diplococcus of Fraenkel, influenced to a very great extent by rapid changes in climate and a low resisting power in the individual. This low resisting power he had noticed most frequently in the chronic alcoholic who rarely recovered from a bad attack of pneumonia. Dr. Raw reviewed at length the various forms of treatment which had been used in the past and were being employed at present and gave it as his opinion that no specific form of treatment influenced the progress of the disease or in any way cut it short. He was of the opinion that the treatment of the future would be antitoxic, the anti-pneumotoxin being either procured by removing serum from a patient who had just recovered from pneumonia or experimentally from immune animals.—Dr. A. T. H. WATERS spoke of the statistics of other hospitals. The mortality from pneumonia varied and the percentage would differ according as complicated cases were included or not. Dr. Waters had tabulated all the cases occurring in hospital practice to the number of 151 with a mortality of 7·28 per cent. He had no doubt of the effects of chill and exposure as an exciting cause. With reference to treatment he thought that many cases would do well without much active interference, and attached great importance to nursing, dieting, and the surroundings of the patient. He had never practised venesection. He attached great value to carbonate of ammonia and in many cases he gave varying quantities of alcohol. In certain adynamic cases he thought quinine was useful and in extreme cases he had seen good results from the inhalation of oxygen and the injection of strychnine with the free use of stimulants. He was in favour of mild counter irritation, but did not approve of blistering in the early stages.—Dr. W. CARTER thought that on clinical grounds one must recognise two different forms of pneumonia—(1) simple and tending to recovery; and (2) septic and very dangerous. He noted the variation in the intensity of the disease in different years and he thought that there was a general epidemic influence that gave undue intensity to the disorder, instancing small-pox in 1881 and influenza at the present time. Referring to treatment, he believed that where the cardio-pulmonary mechanism was seriously disturbed by the sudden invasion, as evidenced by gasping, small pulse, ashy colour, orthopnœa, &c., the abstraction of a few ounces of blood relieved and favoured recovery. There was one stage where opium was useful—viz., where there was a sudden fall of from 6° to 8° of temperature at the period of crisis with the onset of active delirium. Physically except for this fall in temperature the patient seemed the same, the same amount of exudation being present; but vitally he was different, and a good sleep, which then may safely be produced, was most restorative. In all other conditions opium was injurious. In hyperpyrexia he had seen marked improvement by a single cold bath or the application of cold cloths.—Dr. T. R. GLYNN considered that the mortality from pneumonia in Liverpool had been higher in recent years than it was 20 years ago and that deaths now were not infrequent in young people, whereas Barther had only met with two deaths in 212 cases of pneumonia in subjects under 16 years of age. The rate of mortality was also influenced by the length of time elapsing between the onset of the illness and the commencement of treatment. Gripalle's figures emphasised this statement; he found that the mortality amongst patients admitted to the hospital on the first and second days of disease was one in 15, on the fourth day one in eight, and on the sixth day one in four. The pneumococcus often associated with other organisms had been found in the sputum in all of his cases of pneumonia. He discussed the value of leucocytes as an aid to prognosis and referred to the various theories advanced to explain the crisis. In treatment he often resorted to physical measures for reducing the temperature, to large doses of digitalis for procuring sleep, or the hypodermic injection of atropine, and he believed in the efficacy of salicylate of soda and ammonia.—Dr. J. BARR made some remarks, after which the discussion was adjourned until Feb. 8th.

Presentation to the Librarian.—National Association for the Prevention of Consumption.—Exhibition of Cases.—Adjourned Discussion on the Treatment of Pneumonia.

The ninth ordinary meeting of the session was held on Feb. 8th, Mr. EDGAR BROWNE, the President, being in the chair.

Mr. WILLIAM JONES, the resident librarian, having been 21 years in the service of the Medical Institution, the members, wishing to mark their appreciation of his services, had collected a sum of £193 12*s.* 9*d.* (£95 6*s.* being collected by Dr. Rentoul and £98 6*s.* 9*d.* by a sub-committee of the Medical Institution), and the PRESIDENT presented to Mr. Jones a cheque for that sum.—Mr. JONES thanked the members, introducing some interesting reminiscences in his remarks.

Dr. NATHAN RAW proposed:

That it is desirable that a local branch should be established in Liverpool in connexion with the National Association for the Prevention of Consumption and other forms of Tuberculosis.

Dr. W. CARTER seconded the motion, which was carried *nem. con.*

Dr. E. W. HOPE said that Liverpool had, through its city council, its Medical Institution and its boards of guardians as well as, through the munificence of private individuals, taken active measures in regard to tuberculosis, but no branch of the National Association for the Prevention of Consumption had yet been formed there. He moved that the sub-committee appointed in 1898 to deal with questions on tuberculosis should be re appointed.

This motion, seconded by Dr. CARTER, was carried *nem. con.*

Mr. C. G. LEE showed: 1. A patient who had been Accidentally Shot, the bullet penetrating the inner and upper angle of the right orbit, traversing the orbit, missing the eyeball, and finally lodging (as shown by radiographs) in the spheno-maxillary fossa. The boy was in perfect health, and although the bullet was still in the head except for a limited choroidal atrophy he appeared to be none the worse. 2. A youth who had a Piece of Steel Encapsuled with Lymph lying at the Posterior Part of the Retina. When first seen there was traumatic cataract and the foreign body was discovered by the radiograph. The vision was now $\frac{6}{12}$, and the eye was quiet, so Mr. Lee had decided to make no attempt to remove the foreign body.

Dr. E. W. HOPE, in opening the adjourned discussion on Dr. Raw's paper on the Pathology and Treatment of Pneumonia, said that the profession generally were agreed that intemperance predisposed to, and probably actually caused, the fatal results in many cases of pneumonia, but reference to this fact was not made in the death certificates. He had also found in Liverpool that fatal pneumonia coincided with influenza epidemics and that the fatality of these diseases was not associated so much directly with cold as with sudden changes of temperature.—Dr. C. J. MACALISTER, referring to the serum treatment of pneumonia, thought that the argument that the crisis resulted from the production of the antitoxin and that immediate relapse was thereby rendered unlikely was not maintained in the case of broncho-pneumonia where fresh patches of consolidation succeeded one another, and that one attack of croupous pneumonia seemed to predispose to subsequent attacks.—Dr. ABRAM agreed as to the specific infective nature of acute lobar pneumonia. He thought that our present lines of treatment were unsatisfactory mainly because they were symptomatic, and hoped that the work of Washbourn, Pane, and others might give us a curative serum. He pointed out that Maragliano had recently shown that the admixture of digitalin with nutrient media completely inhibited the growth of the pneumococcus, which afforded a valuable suggestion for curative treatment.—Dr. A. G. GULLAN noticed that the mortality in lobar pneumonia had been greater in 1899 than in the three previous years at the Royal Infirmary and he thought that the type of the disease had been more severe constitutionally and the local signs more extensive.—Dr. J. HAY referred to the influence of the alcoholic habit and stated that out of 100 cases which he had watched two-thirds of the entire mortality were those of the alcoholics. He considered that cardiac valvular disease associated with pneumonia was of much less importance than degenerate myocardium, the condition of the latter being more important as a factor in the prognosis.—Dr. MACFIE CAMPBELL saw these cases at their commencement and was responsible for their early treatment, and considered that it was a much more fatal disease now than it was twenty years ago; that fact he attributed to the influenza poison. Pleurisy was a frequent initiating symptom, and for that aconite relieved the pain and fever. Salicylate of soda with carbonate of ammonia were his stand-by; and he used small doses of opium in the form of Dover's powder for the relief of pain. In order to clear up the point as to the influence of alcoholism on the mortality it would be well if death certificates should pass straight from the medical man to the registrar; otherwise the practitioner was placed in an awkward position.—Mr. A. E. DAVIS thought that with careful nursing and treatment the death-rate from pneumonia should be under 10 per cent. He advocated the treatment by carbonate of ammonia and brandy and would never use opium or other narcotics.—Dr. NATHAN RAW, in reply, said that he had included all forms of pneumonia in his statistics, as it was impossible to classify them. He thought that the death-rate of genuine lobar pneumonia was probably about 12 per cent. and that no treatment had any effect in cutting short the disease or to any great extent in influencing its progress. He found that carbonate of ammonia was the most useful expectorant and stimulant, and the combination of chloral and digitalis was useful and soothing. Strychnine was the best drug in threatened heart failure. Oxygen was of little value, and as to alcohol many cases did not require it, but in others it was necessary and was most valuable. It should, however, be of good quality.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Ligature for Femoral Aneurysm.—Hæmaturia.—Increase of Nervous Diseases and Insanity.

THE fifth ordinary meeting of this society was held on Feb. 7th, Dr. JAMES DUNSMURE being in the chair.

Mr. C. W. CATHCART exhibited a boy, aged 15 years, after Excision of the Cæcum for Tuberculous Ulceration and Contraction. The boy had suffered from intestinal obstruction for about six months and had been twice in an infirmary for treatment. He presented all the symptoms of chronic intestinal obstruction, diarrhœa alternating with constipation, and spasmodic attacks of pain. On opening the abdomen a great mass was found to be present at the ileo-cæcal valve and adherent to the surrounding tissues. This mass was freed and excised and the cut ends of the bowel were re-united. The day subsequently to the operation the boy was suffering severely from shock, but after transfusion was performed he began to improve and made an excellent recovery. In six weeks he had gained 16 pounds in weight. The specimen showed the enormous thickening of the intestinal walls and the lumen was narrowed until a No. 6 catheter would hardly have passed.

Dr. ALEXANDER BRUCE showed a man, aged 33 years, suffering from Insular Sclerosis with a remarkable condition of adductor clonus. The affection began to show itself two years ago in the right arm and leg. The patient then recovered but the disease re-appeared in the left arm and later passed to the right arm and so to the legs. There was slight loss of bowel control; there was no great rigidity but a remarkable exaggeration of the deep reflexes. When the patient was seated on a chair and placed his toes on the ground a regular adductor clonus ensued alternating with an extensor clonus, and this continued for from five to ten minutes. Dr. Bruce had noted that there had been a great number of cases of exaggerated clonus seen of late, and he thought that the increased number of disseminated scleroses seen was a result of the influenza epidemic.

Dr. NORMAN WALKER showed a girl, aged 20 years, with an Ulcer on the Left Forearm and asked for a diagnosis. There were neither history nor evidence of syphilis or tuberculosis.

Mr. FRANCIS CAIRD showed two specimens of Sequestra from the Alveolar Margin of the Upper Jaw. The first was from a man, aged 30 years, who had had a primary sore eight years previously, and had undergone several mercurial inunction "cures" abroad. In spite of these, however, being continued over a long time this sequestrum was exfoliated. The second was much larger and was from a man whose primary sore appeared 11 years previously. He was treated in the ordinary way with anti-syphilitic remedies and yet this bone necrosed. Another specimen was a sequestrum of the whole calvarium removed after death from a girl, aged 22 years, who suffered from congenital syphilis. The brain was flattened down with an accumulation of pus and granulation tissue. On the outer surface of the bone evidences of plastic periostitis were seen and on the inner surface small pits due to the granulation tissue.

Mr. DAVID WALLACE showed a case of Fracture of the Radius above the Usual Site of Colles's Fracture.

Mr. J. M. COTTERILL showed a Simplified Form of Trephine which he had devised. It consisted of two pieces only and was readily used and cleaned.

Mr. C. W. CATHCART gave a demonstration of a Plan for using Gauze Dressing Rolled up into Balls as Ordinary Twine was Wound. In this way the piece used might be cut off without soiling or infecting the rest of the roll.

Mr. F. CAIRD showed the patient in a case of Ligature for Femoral Aneurysm. The man was aged 74 years and when Mr. Caird first saw him on Oct. 23rd last he was suffering from a ruptured femoral aneurysm on the right side. The whole thigh was greatly swollen, cold, and pulseless. There was no pulsation in the tibial arteries. The history given was that the man was a rubber-worker and had suffered from pulsating swellings in both inguinal regions for some months. Early in August the right aneurysm increased greatly and latterly had burst. The patient refused to be removed from his dirty dwelling-house, so the operation of ligaturing the vessel was performed there. Bronchitis and retention of urine ensued and the patient would hardly remain in bed, yet in spite of all an excellent recovery was made.

Mr. DAVID WALLACE read a short note on Hæmaturia due to Bilharzia Hæmatobia. He referred to the wide distribution of the disease from the Cape to Cairo and said that it was so frequent a disease in men that the flow of bloody urine was hardly noted by them. He showed that the disease might be contracted by drinking impure water or by bathing. He had observed three cases in Edinburgh, all of whom were young men. The first patient went to Colesberg in South Africa five years ago.

While there he both drank the water and bathed and in two months had hæmaturia. He was much troubled with priapism and seminal emissions, due probably to irritation of the urethra by the ova. *The next patient was aged 21 years* Born in South Africa he had suffered from hæmaturia from the age of 13 years. He was subject to severe attacks of renal colic, so much so that it was thought that he had renal calculus. The cystoscope showed that the bladder was normal in appearance. The third case occurred in a medical student from Newcastle, Natal. He exhibited no symptoms but the passage of blood at the end of micturition, as always occured in slight cases. In examining such cases the small blood-clots should be carefully investigated, as the ova were generally entangled in them. Mr. Wallace had found that salol had done good, but that might be an accident.

Dr. WILLIAM W. IRELAND read a paper on the Increase of Diseases of the Nervous System and of Insanity. After alluding to Professor Erb's last published discourse, in which he dwelt on the increase of the causes of nervous irritation and depression, greater anxiety, hurry and mental toil of life, overtasking at school and the irksomeness of study for the learned professions, the more exciting nature of amusements, the more stimulating character of the diet (these being the causes increased effects were bound to follow), Dr. Ireland could have wished that Professor Erb had afforded some direct evidence of this increasing nervousness which he said had been going on for the last 30 years. The strain of life fell most severely on the middle classes. At the same time the new conditions of their life to-day were not without their compensations If they moved about more they obtained more frequent amusement and change of air; if letters and telegrams too often claimed their attention and disturbed their repose they often banished uncertainty and anxiety. Drunkenness had become less prevalent both amongst the upper, middle, and, it is reasonable to believe, the lower classes. In general they led more secure lives than their fathers did and the condition of the working-classes had greatly improved, both financially and physically. Still, Dr. Ireland thought that the strain upon the nervous system was getting greater, at least for the middle and upper classes, and consequently they might expect more nervous derangements and breakdowns. To make a general opinion like this, evident by exact inquiries, was on the face very difficult. There were statistics to answer the questions as to whether insanity, idiocy, or the number of suicides were increasing; but as to whether other forms of nervous disease had become more frequent was a question which could hardly be approached in that way, as many of such disorders did not affect the mortality returns or appear as results in statistical tables of any kind. Dr. Ireland addressed to a number of medical men the following questions: (1) Have you found since you began to practise medicine that there had been an increase in the relative frequency of diseases of the nervous system? (2) Have new forms come into prominence? (3) Have you observed any change in the type of old diseases? To these circulars a good many interesting replies were received and several pointed out the dangers of fallacy in answering these questions. The most trustworthy answers might be expected from medical men who had long practised in one district in the country or in small towns, treating every class of patients alike, but these gentlemen who answered the inquiries all declared that they saw no reason to affirm that diseases of the nervous system had increased in their districts relatively to other diseases. Some physicians of experience practising in large towns were of the same experience. On the other hand, some physicians of reputation in the same towns, but presumably treating a different class of patients, had stated that nervous diseases had increased in frequency during the last 20 years. Most of the latter consider that the increase has taken place in the lighter forms, especially in neurasthenia. Few physicians had noticed any change in the type of disease. Dr. Byrom Bramwell thought that there had been an increase in some of the functional neuroses and he was of opinion that disseminated sclerosis had, during the past few years, become commoner and that that was due to an antecedent attack of influenza in many cases. Dr. Ireland stated that monotonous work demanding severe and unremitting attention was most trying for the nerves and assisted in causing mental derangement Thus nervous diseases and insanity were especially common with telegraphists, letter sorters, and persons who had to check mechanical labour. From all the answers received Dr. Ireland judged that there had been no noticeable increase in the number of diseases in country districts and in small towns, but there was some evidence that there had been an increase in those complaints in large towns, especially in functional disorders such as neurasthenia. Probably this increase affected some classes and persons of special pursuits more than others. Dr. Ireland made an exhaustive statistical inquiry as regards the incidence of severe forms of nervous disease in Scotland. He found that those nervous diseases which were assigned as causes of death were less frequent in Scotland than in England, and figures were given to show this and other facts. These statistics seemed to Dr. Ireland that it was not going in advance of the evidence to pronounce that the graver forms of diseases of the nervous system had increased in Great Britain as they were said to have done in France and Germany during the last 40 years In Scotland there seemed to have been a stoppage in the increase from 1885 to 1897 which Dr. Ireland hoped indicated that the rise in the death-rates from these maladies was not fatally progressive. The increase in the number of suicides was most marked in great cities and seemed to be steadily progressing in every country in Europe excepting Norway. In Scotland the increase from 1865 to 1894 had been stated to be from a rate of 40 to a rate of 54, or an increase of 35 per cent. The same steady increase in the number of the insane went on in Scotland as in England, and there had been the same startling rise in 1897 and in 1898 which had distanced all arithmetical explanations In 1898 there was an increase of registered lunatics of 487, of whom 49 were private patients and 438 were pauper patients. The census returns for Scotland showed in 1871 one insane person for every 494 of the population; in 1881 one insane for every 444; and in 1891 one insane for every 385. Of the causes assigned for this increase Dr. Ireland was willing to allow something for the accumulation of chronic cases in asylums; the greater readiness to grant admission to all cases of mental failure aided by the 4*s.* grant given from the Imperial Exchequer to ease the local rates; and the diminished number of discharges; yet Dr. Ireland believed that that would not account for the whole increase of insanity. Again and again had those who tried to explain it away been obliged to make the premisses of their arguments more ample in order to account for the striking increase of admissions to asylums. They had now to deal with a real and considerable increase in the number of the insane and this was but a part of an advance along the whole line, an increase in the frequency of nervous diseases, in suicide, and in insanity.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Tracheotomy in Diphtheria.

A MEETING of this section was held on Jan. 26th, Dr. J. W. MOORE, the President, being in the chair.

Mr. H. GRAY CROLY detailed the symptoms of a case of Diphtheritic Inflammation of the Larynx and Trachea in a child, two years old, admitted recently into the City of Dublin Hospital (detached Drummond Hospital) for infectious cases) under the care of Sir George Duffey. The child was in a most critical condition, with urgent dyspnœa, lips bluish, and signs of collapse. With much difficulty the fauces were examined. The tonsils were considerably swollen and there was some evidence of a whitish patch on one side High tracheotomy was performed by Mr. Croly; the child got immediate relief and fell into a peaceful sleep, but in a few hours became very restless, gradually got worse, and died within 12 hours of the operation. The larynx and trachea were removed in a few hours, but no further examination was made. The larynx and trachea with the silver tube *in situ* were exhibited. The epiglottis was thickened and hard; the folds at the entrance of the larynx were considerably thickened. On opening the windpipe a bluish false membrane easily detached was found at one side. Mr. Croly gave a sketch of the history of tracheotomy in such cases from the time of Hippocrates and read extracts from the writings of Professor William Henry Porter, Trousseau, Cheyne, Millard, and Peters. He quoted the statistics of Peters (in Trousseau's Medicine), 15 operations on girls between two and three years and 11 operations on boys of the same age; all were fatal. The largest proportion of recoveries was in children over five years.—The PRESIDENT, Sir GEORGE DUFFEY, and others discussed the case.

SECTION OF SURGERY.

Epithelioma of the Glottis and Larynx.—Goitre.—Foreign Body in the Knee-joint.—Aneurysms.

The first clinical evening of this section was held on Jan. 19th, Mr. R. L. SWAN, the President, being in the chair.

Mr. H. GRAY CROLY exhibited a male patient, aged 42 years, suffering from Epithelioma of the Epiglottis and Larynx. There was a growth attached to the epiglottis There was no history of syphilis. The patient became emaciated and suffered from considerable dyspnœa. Tracheotomy was performed under chloroform on Nov. 14th, 1899 The veins were very large. He had shown the growth to surgeons and specialists and they had agreed with his diagnosis The glands, which had been very large, had gone down very much, which seemed to indicate that tracheotomy stayed the progress of the disease. There was no difficulty either in producing or continuing the anæsthesia.—Professor BENNETT, Dr. J. KNOTT, the PRESIDENT, and others discussed the case.

Mr. JOHN LENTAIGNE exhibited a patient, aged 20 years, from whom he had removed the greater portion of a very large Goitre on Sept. 4th, 1899. The case was of interest inasmuch as the operation had been done entirely under local anæsthesia by cocaine It was well known that Professor Kocher habitually used this method with success in cases of severe goitre, but Mr. Lentaigne was not aware that so far anyone in Ireland had done so. The result had been in every way most satisfactory The goitre consisted of three lobes, a very large right lobe, a large middle lobe, and a comparatively small left lobe. On account of the patient's dyspnœa Mr. Lentaigne preferred local anæsthesia to ether or chloroform During the entire operation immunity from pain was enjoyed by the patient, who showed no discomfort of any kind, except for a moment, when the upper horn of the growth which burrowed deeply under the larynx was being extracted. Very little blood was lost as the vessels were tied before being cut. The goitre proved to be of the colloid variety. The left lobe of the goitre, which remained, had shrunk since the operation to such an extent as to be now barely noticeable and the patient was in excellent health and condition The incision employed was the collar incision recommended by Professor Kocher. The cocaine was used hypodermically and was injected along the line where the incision was subsequently made; he did not think it would have any effect if applied to the surface of the skin. From time to time during the progress of the operation a little cocaine was dabbed on the tissues He commenced his incisions as soon as he had completed the injections.—Mr. H. G. CROLY, Dr. KNOTT, and Mr. F. T. HEUSTON discussed the case

Mr. R. L. SWAN showed a man, aged 22 years, from whose Knee, two years ago, he had removed a Loose Cartilage in the ordinary manner at the inner side. Soon afterwards he began to complain of symptoms indicating the presence of another similar body in the joint. Nothing, however, could by the most careful examination be felt. Mr. Swan waited for some time in the hope that the body would become detached, but the constant occurrence of locking of the joint, followed by synovitis, had the effect of rendering the limb useless. A skiagram showed the outline of a foreign body in the joint. A lateral incision at the outer side was made, but this proved inefficient. Accordingly, a transverse section of the patella was made, and the body was found attached by a strong fibrous envelope to the intercondyloid notch. The patient had now a perfect joint.

Mr. F. T. HEUSTON brought forward a man for whom he had ligatured the left subclavian artery in its third stage for Traumatic Subclavio-axillary Aneurysm four years since. At the time of the operation he was 50 years of age and had been 20 years in the army He was admitted to the Adelaide Hospital in February, 1896, suffering from severe pain in his shoulder, left arm, and back, which was then continuous, although it had been for some time at first intermittent. The superficial veins of the left arm were tortuous, the arm being also swollen and œdematous. The clavicle was raised by a tumour occupying the supra- and infra-clavicular regions, presenting a well-marked bruit, distensile pulsation, and thrill. There was well marked difference of the pulse in the right and left arms. The artery was ligated by catgut applied close to the outer side of the scalenus anticus muscle; the patient left the hospital 23 days after the operation, and resumed his ordinary occupation, which he has filled since without any return of symptoms.

Mr. ARTHUR CHANCE exhibited a man, aged 33 years, whose Popliteal Artery had been Ligatured for Aneurysm. He had suffered from syphilis. His work entailed the lifting of very heavy weights Early in May last he noticed a dull pain at the back of his right knee. There was no noticeable swelling at the time but it came on afterwards. On June 12th he was admitted to the Mater Misericordiæ Hospital, where he was found to have in his right popliteal space a tumour of about the size of a Tangerine orange which showed all the classical signs of aneurysm The right foot was much swollen and œdematous On June 21st the artery was exposed at its upper part by an incision parallel to the adductor magnus. The hamstring tendons were drawn backwards, the artery tied with silk, and the wound closed. There was no pain or rise of temperature and the wound healed by first intention. It was now six months since he had returned to his work and there was no sign of trouble in the aneurysm. Mr. Chance tied the popliteal artery—first, because the man's foot was very œdematous and it was necessary to choose the method which would best establish the collateral circulation; secondly, because the man was young; and, thirdly, because he was occupied in exceptionally heavy work. There was a considerable distance between the aneurysm and the ligature.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting was held on Feb 2nd, Dr. J. B. Ball, the President, being in the chair —Mr. Alfred Cooper, in opening a discussion on the Treatment of Primary and Secondary Syphilis, said that before the surgeon treated primary syphilis he must be very careful of the diagnosis of the sore, as many cases were met with in which induration was of an inflammatory nature, frequently due to the application of irritating substances In considering the treatment of the sore the question as to whether abortives were useful or not was one of considerable importance. He placed no reliance whatever either in excising the indurated sore or in attempting to destroy it by any cauterant. The induration was the result of a previous and complete contamination of the system It was now an established fact that mercury was the best agent to be relied upon for treating the indurated sore and its use should be commenced as soon as the diagnosis was made. The application to local sores should be, he thought, blackwash or equal parts of mercurial ointment and vaseline. They might get a sore running into phagedæna, when it would be unwise to use any mercury at all. In that case the local treatment would consist of putting the patient into a hot bath until the sore assumed a healthy character. He had seen the most serious results occur when mercury had been given. It was of great importance that the mercurial treatment should be carried out thoroughly and systematically. It had been stated by Dr. Gowers that syphilis was incurable, but he did not agree with that dictum. It was a matter of great difficulty to tell when a patient was cured, but they could speak with greater confidence if they had seen that a long and efficient course of mercury had been undergone. There were numerous methods by which mercury could be introduced into the system. He had found tannate of mercury to possess great advantages over other drugs. It was quickly absorbed and quickly eliminated and it did not produce stomatitis to such a degree as other preparations of mercury. It could be given in doses of from one to two grains in the form of pills three times a day. Treatment should be continued for two years. He had found intra-muscular injections of mercury most successful. Since 1894 he had used injections of sozoiodol of mercury (one eighth of a grain) once a week with great success. Patients were being treated at the Lock Hospital at the present time by intravenous injections of mercury The treatment was originally suggested by Baccelli in 1893. Cyanide of mercury was considered the best preparation to use; it was considered to have immediate effect on the syphilitic lesions, a chancre often showing signs of healing within 24 hours. Mercurial baths had of late years fallen into disuse Regularity of living and abstinence from alcohol were of great [illegible] If [illegible] were necessary he allowed a light beer, claret, or Moselle.—Mr. Swinford Edwards pointed out the difficulties in the early diagnosis of syphilitic sores and said that they must be content to keep doubtful cases under observation until the doubt was cleared up. At the same time it was very important to begin mercurial treatment at the earliest possible moment. In the treatment of primary and secondary syphilis he was a believer in small doses of mercury continued over long periods. When mercury upset the gastro-intestinal canal intra-muscular injections of sozoiodol of mercury were of great use. The worst subjects for syphilis were the alcoholic and tuberculous and in both classes treatment must be modified to suit the particular case.—Dr. J. A. Shaw-Mackenzie thought that the physician could not be accused of trespassing on the ground of the surgeon, because before the days of Hunter few or no surgeons had written on the subject of syphilis, and in the reign of Queen Elizabeth surgeons who meddled with such cases were liable to prosecution by the College of Physicians unless they were members of the Apothecaries' Company. He did not think it possible to separate the pathology of syphilis from its treatment. Every grade of syphilitic severity was met with, and the causes of aggravation as well as of mitigation were many, apart from this or that particular method of treatment. Many suppurative sores and chronic discharges in both sexes were of syphilitic origin, more quickly cured by modified mercurial treatment; which cases with pelvic trouble in the woman, if recognised and treated accordingly, would probably never reach the knife of the operating gynæcologist He thought that the external methods of administration of mercury better fulfilled the theories of the elimination of the virus through the skin, phagocytosis and leucocytosis, apparently underlying natural cure; and from long association with the late Mr. Henry Lee he advocated the method of calomel fumigation.—Dr. Phineas Abraham said that there was great difficulty in persuading patients to continue treatment for a sufficiently long period; he suggested, therefore, that arrangements might be made for the reception of syphilitic patients into sanatoria where they could be properly watched and treated He used small doses of mercury with chalk with compound powder of ipecacuanha given frequently for at least a year, with mild mercurial ointments for the cutaneous manifestations —Mr. McAdam Eccles said that in addition to the mercurial treatment it was very necessary for the patient to have the best hygienic surroundings—fresh air, good food, and warm clothing—and to avoid alcohol. He agreed, therefore, with Dr. Abraham that the treatment of the affection in sanatoria might become a factor of considerable importance —Mr L. A. Bidwell gave a brief account of continental methods of treating syphilis, particularly as practised at Aix-la Chapelle —The discussion was continued by Mr. Herbert Paterson, Mr. Rickard Lloyd, Mr. C. R. B. Keetley, Mr. G. E. Twynam, Mr. H. De Méric, Dr. Rayner Batten, Mr. A. R. S. Douglas, Mr. Percy Dunn, and Mr. Alfred Cooper.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 16th, Mr. W. Horrocks, the President, being in the chair.—Dr. F. W. Eurich gave a microscopical demonstration illustrating Epitheliomata. —Dr. James Kerr communicated a paper on Inflamed Corneal Ulcers and showed illustrative preparations, together with the record of 100 cases treated by operation. The disease was most common in dusty weather and in people following dusty occupations. It was frequently traumatic in origin. Workers in soil and stone were the most frequent sufferers. Its incidence increased rapidly with age after 35 years. The spreading serpiginous ulceration, which was the most serious form, was due to pneumococci, which were confined to the cornea, the deep symptoms being due to the toxins produced. The galvano-cautery and paracentesis were held to be the best treatment, while scraping of the ulcer was not advised. Great importance was attached to early diagnosis and energetic treatment —Dr. H. C. Major related a case of Trance which had a fatal termination.—The patient was a woman, aged 50 years, and was seen in consultation with Dr. G. H. Moorhead. She lay almost as one dead; there was intense pallor of the skin and the muscles were relaxed. The respirations were exceedingly shallow and the heart's impulse was very weak. The conjunctival and other reflexes were absent and she could not be roused to show any evidence of consciousness. The onset had been rather sudden three days previously; there were at first some transient spasmodic movements of the limbs. She continued in this state for about three weeks and finally died from exhaustion She had been fed artificially by enemata and by the nasal tube. Physical examination was negative. The optic discs were normal. Post-mortem examination revealed nothing except anæmia of the nervous system and organs generally. The case was diagnosed as one of death trance—a very rare affection. The symptoms appeared to depend on profound functional inhibition of the nerve-centres. As regards diagnosis, uræmia, diabetic coma, cerebral tumour, and hæmorrhage must be eliminated, but a case of trance declared itself in a short time. Practical considerations in the treatment of such a case were: examination of urine for albumin and sugar to exclude uræmic and diabetic coma, regular nasal feeding, the administration of amyl nitrite, and the injection of normal saline either into cellular tissue or the rectum. Faradaisation of the surface of the dry skin with electric brush was worthy of trial. Should death appear to take place they must be exceedingly careful before allowing anyone to act on that supposition It was an acknowledged fact that patients had almost been put into their coffins while in a condition of trance. The faradaic current should be applied to the muscles. Muscular contractions ceased three hours after death (care must be taken to see that the current employed would cause contractions of normal muscles). A case was recorded by Rosenthal in which, 33 hours after apparent death, the muscles continued to react to faradaism; and 44 hours after the patient awaked.—Dr. H. J. Campbell mentioned a case in which the patient had twice been put into her coffin and subsequently recovered.—Mr. J. B. Hall and Dr. J. H. Bell made remarks and Dr. Major replied —Dr. Mitchell, showed a specimen from, and read notes on, a case of Ectopic Gestation. The patient was a married woman, aged 38 years. She had menstruated ten days before being seen. She had suffered from indigestion for six weeks. The pulse was 80 and the temperature was 98 8° F. The illness commenced on August 6th with severe pain and vomiting; it was thought to be a case of autumnal gastro-enteritis. The legs were extended and the abdomen was tympanitic. The next day the distension had increased and there was no pain or vomiting. The bowels were not moved. The temperature was 101° and the pulse was 88 On the 9th the patient was much worse and there was coffee-ground vomit On the 10th the pulse was 104; there was no pain, but the patient was pallid and there was doubtful dulness in the flanks on percussion. On the 11th the pulse was uncountable and the pallor had increased. Hæmorrhage was diagnosed and the patient died before anything could be done. At the post-mortem examination the whole peritoneal cavity seemed to be filled with blood.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Feb. 8th, Dr. W. J. Smyly, the President, being in the chair.—Dr. Arthur Giles showed a specimen of Myomatous Uterus removed from a patient with Glycosuria Hysterectomy was performed on account of menorrhagia and pressure symptoms; and as she suffered also from umbilical hernia a radical cure was performed at the same time. Glycosuria was first noticed about a week before the operation; on previous occasions when the urine had been examined no sugar was present. The patient was a stout florid woman, aged 44 years; she had neither thirst nor polyuria and diabetes could therefore be excluded. The recent appearance of sugar in the urine rendered it unlikely to be due to pressure from the myoma, as might sometimes happen with ovarian tumours, and Dr. Giles believed it to be of nervous origin in this case. The patient made an uninterrupted recovery and the case was important as showing that functional glycosuria was not a contra-indication to such a grave operation as hysterectomy.—In the discussion on this specimen remarks were made by Dr. Travers, Dr. Macnaughton Jones, Dr. Heywood Smith, Dr. W. H. Bourke, Dr. Inglis Parsons, and Professor Japp Sinclair.—Dr. F A. Purcell showed (1) a large Pyosalpinx, together with Uterus, removed by Sub-peritoneal Hysterectomy; and (2) a Fibro-myoma of Unusual Shape springing from the Uterine Fundus; it was a sausage-shaped mass ten inches long and of the thickness of a man's wrist; in its fresh state it resembled a stunted cactus plant.—Remarks in discussion were made by Professor Japp Sinclair, Mr. Furneaux Jordan, Dr. Macnaughton Jones, Dr. Inglis Parsons, and the President —Dr F. Winson Ramsay read the notes of a case of Chronic Tubal Inversion of the Uterus The patient was aged 48 years; three days after the birth of her last child 14 years previously, she had castor oil, and while on the bed pan the uterus came down into the pan The medical man came within three quarters of an hour and pushed it back into the vagina From that day she had always had a slight bloody discharge After 12 months she consulted a medical man who introduced a pessary, which she took out once a week for cleaning In March, 1898, a larger pessary was given her, and as she had pain in the back and bearing down she was told not to take it out so often In May, 1898 she noticed that urine was always running from her In the following September she was unable to remove the pessary and it had to be taken out in pieces under chloroform, urine then ran away more than ever Examination revealed at once a completely inverted uterus not much larger then a normal uterus and covered with stinking slime and phosphates, the base of the bladder was completely gone, exposing the fundus, and the edges were composed of a ring of dense cicatricial tissue After rendering as aseptic as possible, the uterus was removed with scissors on Jan 3rd, 1899, operations for closing the fistula were performed on six occasions up to August of last year She was now quite well, could do her work, could hold her urine for three hours during the day and had not to get up at night —Dr Clement Godson thought the best treatment had been adopted in this case, in view of the vesico vaginal fistula it would have been useless to try to restore the uterus Otherwise it might have been attempted by means of an Aveling's repositor, for this could sometimes be effected when an inversion had existed for many years A Zwancke's pessary should never be allowed to remain *in situ* for any length of time, but should be removed every night and replaced in the morning —Dr Macnaughton Jones congratulated Dr Ramsay on the method adopted in closing the fistula It was the plan first suggested by Dittell and adopted by Howard Kelly of transplanting part of the vagina into the bladder There could be no doubt as to the propriety of removing the uterus in such a case —Professor Japp Sinclair related a case in which he found a vesico vaginal fistula in a patient who gave a history of forceps delivery There was considerable loss of tissue and it seemed to him that the only thing to do was to turn the uterus itself into the bladder. This he did and the patient went on menstruating through the bladder without any inconvenience This showed that the surface of the uterus as well as that of the vagina need cause no bad results when turned into the bladder —After some observations by Dr J Oliver Dr Ramsay replied —The President then delivered his Inaugural Address in which he dealt firstly with the question of the practical teaching of Obstetrics and Gynæcology, and secondly with the subject of the Registration of Midwives —On the motion of Dr Macnaughton Jones, seconded by Dr C H F Routh, a hearty vote of thanks was accorded to the President for his address which he was requested to allow to be printed in the Transactions of the society

SHEFFIELD MEDICO CHIRURGICAL SOCIETY —A meeting of this society was held on Feb 1st, the President, Dr D Burgess, being in the chair —The President showed the following cases (1) A boy with Pseudo-Hypertrophic Paralysis, (2) a woman with Argyria, and (3) a case of Cerebellar Ataxia of over a Year's Duration There were no optic neuritis, no headache, no vomiting, and no evidence of syphilis or tuberculosis —Dr Arthur Hall showed a severe case of Tertiary Syphilitic Ulceration affecting the Left Orbital and Nasal Region The patient had acquired syphilis whilst in the army and had only received six weeks' treatment after the primary infection —Dr Sinclair White showed the following cases 1 A man, aged 54 years, on whom he had performed Suprapubic Prostatectomy for Marked Enlargement of the Middle Lobe of the Prostate with Vesical Calculi The bladder, which had been in a state of atony for several years, had recovered its tone and the patient was greatly benefited by the operation 2 Four cases of Resection of the Large Intestine for Cancer In one case the disease involved the cæcum In the other three it was situated in the sigmoid and one of the latter was suffering from acute intestinal obstruction and resection was preceded by making a temporary artificial anus above the growth In all of the four cases a Murphy's button was employed and they all made a good recovery One patient was only 29 years of age 3 A Myomatous Uterus removed Abdominally with Vaginal Drainage The patient made a good recovery notwithstanding a hernia of the small intestine through the abdominal wound which was relieved on the third day —Mr A M Connell showed the following cases illustrating conservative surgery of bone 1 A lad, aged 18 years, who had had his Left Hand caught in a Hay chopper, the proximal phalanges of the four fingers being divided and the fingers hanging by the flexor tendons and the tissues of the palmar surface The phalanges were drilled and brought together with silkworm gut sutures and the wounds had quite healed on the eighth day The patient had now a good grip, with unimpaired extension, but flexion was limited 2 A man, aged 32 years, who had a Compound Comminuted Fracture of the Upper Fourth of the Left Tibia involving the Knee-joint. Some loose pieces of bone were removed and a large wedge shaped part carrying the internal tuberosity was wired to the shaft Three subsequent operations for small fragments of bone were performed The result was a perfect movement of the joint, though the limb was somewhat bowed owing to the dropping of the internal tuberosity The patient had resumed work a year after the operation 3 Comminuted Fracture of the Left Clavicle in a man Attempts at reduction being futile two silver wire bracelets were passed round the fragments, the ends of the wire were bent down on to the bone and interlocked, and the periosteum was united over these The wound was dressed on the eighth day and the stitches were removed The result was gratifying, as the position was good and all the movements at the shoulder were normal —Professor C F Myers Ward demonstrated the most modern and approved forms of Kymograph Artificial Respiration Apparatus, Volumetric Apparatus and other Physiological Accessories

OBSTETRICAL SOCIETY OF LONDON —The annual meeting of this society was held on Feb 7th Mr Alban Doran, the President being in the chair —The reports of the treasurer, the honorary librarian and the chairman of the Board for the Examination of Midwives were received, adopted, and ordered to be printed in the next volume of the Transactions —Sir William Overend Priestley and Dr James R Chadwick were elected honorary Fellows of the society —Votes of thanks were passed to the retiring vice-president members of council, honorary secretary, and honorary librarian —The President then delivered the Annual Address, including the usual review of the work of the past year During 1899 the society lost ten ordinary Fellows, but none on the honorary list Obituary notices of the ten deceased Fellows were then read; the list included one original Fellow, Dr J A Duncan of Covent Garden; Mr Lawson Tait on whose work the President dwelt at some length; Mr G. F Farr of Kennington and Dr J M Bright of Forest Hill, who both died on Jan 11th, Mr W R Dambrill Davies, once assistant to Dr Clay of Manchester, Mr Clement Pound of Odiham, Hants, Dr A T Gibbings of Dalston, Dr T Cargill Nesham, Lecturer on Midwifery at the University of Durham College of Medicine, Newcastle; Dr Samuel Johnson of Stoke-on Trent, and Dr James Ford of Eltham The officers and other members of council were appointed for the year 1900 as follows —President Mr Alban Doran Vice Presidents Dr John W Byers, Dr William Radford Dakin, Dr John Phillips and Dr. Jamieson Boyd Hurry Treasurer Dr James Watt Black Chairman of the Board for the Examination of Midwives Dr Percy Boulton Honorary Secretaries Dr Herbert R Spencer and Dr Amand Routh Honorary Librarian Dr Montagu Handfield Jones Other members of Council Dr Augustus W Addinsell, Dr A H Freeland Barbour, Dr George Francis Blacker, Dr Robert Boxall Dr Francis Henry Champneys Dr Thomas Vincent Dickinson, Dr Angus Fraser, Dr Arthur Edward Giles, Dr George Ernest Herman, Dr Thomas Robert Lombe, Dr John Dysart McCaw, Dr Ewen John Maclean Dr Hugh James Moore Playfair Dr William London Reid, Dr George H Drummond Robinson, Dr William Japp Sinclair, Dr Arthur Francis Stabb, and Mr, John William Taylor The following specimens were exhibited —Dr Amand Routh Conjoined Twins —Dr. W S A Griffith Cancer of the Ovary —Mr, Cuthbert Lockyer Intra ligamentary Oophoritic Cystoma

NEWCASTLE-UPON-TYNE CLINICAL SOCIETY —A meeting of this society was held on Feb 1st Mr H B Angus the President, being in the chair —Dr A H Hobbs showed a female suffering from Focus tube Dermatitis Her knee had been subjected to x ray examination six months ago for loose body in the joint; 16 days later the skin which had been most exposed to the rays developed an inflammatory condition, and in from three to four weeks a well-marked bulla appeared. An ulcer which was intractable to treatment resulted and was still present —Mr. George Foggin discussed at some length the five different views set forth as the possible causation of the condition —Dr. W. Martin stated that he had now employed the x rays in 200 cases, and this was the first case in which untoward symptoms had arisen.—The President, who is in charge of the x ray department at the Newcastle Royal Infirmary, had only seen one case in his practice.—Mr. T. G. Ouston showed a child, aged five months, with Spina Bifida. The tumour was of the size of a fœtal head, entirely covered with skin and translucent except just beside the spine There was no paralysis, and he considered that the general and local condition of the child warranted the performance of excision.—Dr. T. Beattie urged that the argument against operation in a case of spina bifida should be an increase in its size out of proportion to the size of the child.—Dr. R. P. R. Lyle delivered an address on the Use of Midwifery Forceps He strongly deprecated the too frequent use of forceps and considered 2 per cent. an ample average. No pains should be spared by the obstetrician to avoid their use by a careful management of the first and second stages of labour. If forceps were inevitable the easiest and safest operations should be aimed at. He considered turning preferable to the high operation. More care should be exercised to preserve the child's life. Forceps should not be applied to the breech or the after-coming head.—A discussion ensued in which the President, Dr. Hobbs, Mr. Ouston, Mr. Foggin, Dr. Campbell, Dr. Beattie, and Dr. W. E Alderson took part.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 24th, Mr. Alexander Miller, the President, being in the chair.—Dr. J. Lindsay showed the Fœtus and Decidua of a Tiger, of a large Fruit Eating Bat, and of a Marmoset.—Dr. J. Edgar showed a Ruptured Hæmatoma of the Left Ovary, the cause of a Pelvic Hæmatocele.—Dr Alexander MacLennan read a paper on the Involution of the Puerperal Uterus. The following points were noted: (1) the method of measuring and the precautions required to avoid fallacies; (2) the physiological circumstances influencing involution, such as age, parity, lactation, time of taking measurements, posture, &c; (3) the pathological lesions affecting involutions with charts to demonstrate the various conditions; and (4) diagnosis, treatment, and prognosis. (*a*) Diagnosis: the observations of involution aided in separating minor from major cases of fever and were especially careful in differentiating the minor cases; (*b*) treatment: the measurements of the uterus gave indications for the administration of ecbolics or cathartics, the intra uterine douche, &c; and (*c*) the prognosis —Dr W. L. Reid showed the child from his case of Ectopic Pregnancy and read some part of his paper. He considered especially the question whether it was really a case of interstitial pregnancy. The points he laid special stress upon were the size of the empty uterine cavity, which was large even for an extra-uterine pregnancy, and the bulging into the cavity of the antero lateral wall of the organ —Dr R. Jardine read notes of Three Fatal Cases of Puerperal Septicæmia of Unusual Origin. The first case was a woman who while pregnant poisoned her finger with a splinter of wood The second case was a woman admitted to the Maternity Hospital moribund She had been in labour for five days and was septic to the last degree. A dirty old woman had been looking after her. The third was a case where infection had occurred from an old retro-peritoneal abscess.

CARDIFF MEDICAL SOCIETY.—The ordinary monthly meeting of this society was held on Feb. 2nd, Dr. P. Rhys Griffiths, the President, being in the chair — The minutes of the last meeting having been read and confirmed, Dr. John Williams showed three specimens and two drawings of Solid Tumours of the Ovary, varying in weight from two to four pounds, removed by laparotomy. Four of the tumours were associated with well-marked ascites, were malignant, and were removed from patients ranging in age from 19 years to 66 years, and the fifth, a solid fibroma, unassociated with dropsy, was removed from a patient aged 39 years. Dr. Williams also exhibited a drawing of a small Papillomatous Cyst springing from the oöphoron with a thick deposit of secondary sprouting papillæ over the pelvic peritoneum. This was removed from a patient, aged 60 years, and was asso ascites.—Mr. E. T. Collins made some remarks.—Dr. A. P. Fiddian described a case of Pediculi Palpebrarum and showed the specimen, commenting upon the rarity of the condition.—Mr E T. Collins showed a large Nodular Uterine Fibroid removed by Pan-Hysterectomy. The tumour was in part impacted in Douglas's pouch and had contracted extensive adhesions with the intestine. The patient made a good recovery.—Mr. William Sheen showed a series of lantern slides to illustrate the Topographical Anatomy of the Mastoid Antrum and the operations connected with it. The anatomical details underlying the various complications of antral disease were briefly outlined.—Dr. D. R. Paterson called attention to the importance of the persistence of the fœtal petro-squamous sinus in determining the route of the infective process —The President and Mr. Cornelius Griffiths also made some remarks and Mr. William Sheen replied.

FOLKESTONE MEDICAL SOCIETY.—A meeting of this society was held on Feb. 2nd, Dr. W. J. Tyson, the President, being in the chair.—Dr. Hoggan Ewart read a paper on Patent and Quack Remedies. A quack was defined as "a boastful pretender to knowledge which he did not possess." Patent medicines were almost always a financial failure whilst proprietary ones were not. In the former the ingredients were known, whilst in the latter they were not. The authority of the Queen's Patent gave a false impression to the ignorant and Government protected the privilege of proprietors of quack medicines by paying for the prosecution of infringements —The society passed the following two resolutions unanimously: "1. That this society is of opinion that the use of patent and proprietary medicines is largely on the increase and is a public danger. 2 That the unrestricted sale of powerful drugs, such as hypnotics and antipyretics, in tablet form is largely on the increase and is a public danger."

NEUROLOGICAL SOCIETY.—The annual meeting of this society was held on Feb 8th —The following were elected officers for the ensuing year:—President: Dr. Augustus Waller. Vice-Presidents: Dr. W. Julius Mickle and Mr. Herbert William Page. Council: Mr. C. A. Ballance, Dr. W. H. Gaskell, Mr. R. Marcus Gunn, Dr. Henry Head, Dr. B. Lees, Dr. C Mercier, Dr F W. Mott, Sir Felix Semon, Dr. James Taylor, and Dr. W. Hale White Treasurer: Dr. Charles E Beevor Editor (*ex-officio*): Dr. A de Watteville. Secretaries: Dr J. S Risien Russell and Dr. W. S. Colman. —Dr. A. Waller delivered his Presidential Address on the Excitability of Nervous Matter, with special reference to the Retina, which was illustrated by numerous tracings and diagrams —A vote of thanks to the President for his address was moved by Sir William Broadbent, F.R S, and seconded by Dr. C S. Sherrington, F R S.

Reviews and Notices of Books.

A System of Medicine by Many Writers. Edited by THOMAS CLIFFORD ALLBUTT, M A, M.D. Cantab, LL D. Glasg., D Sc. Vict, F R C P Lond., F.R S, Regius Professor of Physic in the University of Cambridge, Fellow of Gonville and Caius College. Vol. VIII London: Macmillan and Co. 1899. Pp 998. Price 25*s.* net.

THIS is the concluding volume of this excellent System of Medicine and is devoted chiefly to mental diseases and diseases of the skin, but it contains also a few of the less easily classified affections of the nervous system. The first article is on Craft Palsies by Dr. G. V. Poore Of all the paralyses belonging to this class more than 90 per cent. are cases of writer's cramp, partly perhaps because this form of movement is specially prone to lead to this condition, but chiefly on account of the fact that the occupation of clerk outnumbers all other occupations in which special neuroses are apt to occur. Dr. Poore has only seen two cases which could fairly be regarded as examples of "telegraphist's cramp," and both of these were in all probability cerebral in origin. In the case also of "hephæstic palsy" occurring in those who wield light hammers for forging nails or penknife blades the author believes that the fatigue is cerebral rather than muscular For the prevention of writer's cramp Dr Poore advises that children should be trained to a certain degree of ambidextry and that our strokes in writing should be vertical rather than oblique The typewriter is recommended for the use of those who suffer from writer's cramp, but this instrument is not applicable to bookkeeping

Professor J Chiene in an account of Spasmodic Torticollis, thinks that the disease is probably central in origin and that neurectomy of the spinal accessory nerve is the best treatment in ordinary cases, but that as a last resource in severe cases a portion of the motor area of the cerebral cortex may be excised

The articles on Facial Spasm and on Tetany are from the pen of Dr Risien Russell, and the latter paper has a very useful bibliography in which the references are classified according to the chief topics dealt with Dr J A Ormerod's paper on Hysteria is a valuable account of this troublesome disease, he does not appear to be inclined to accept the results of the researches of Gilles de la Tourette on the alteration in the composition of the urine after hysterical attacks

Dr P Manson gives an interesting description of Latah, a somewhat obscure disease met with in the Malay Peninsula and in Java The patient is in a condition like that of a man under the influence of hypnotism and will say words and do actions on the suggestion of others Dr Manson considers latah to be related to various psychopathies, such as the "ikota ' of the Samoyeds and as allied to the curious epidemics of religious ecstasy which were met with so widely in the Middle Ages

The late Dr Hack Tuke has contributed a short article on Catalepsy in which he states that no definite knowledge of the pathology of the condition has yet been gained

It has been customary to look upon neurasthenia as a special product of the high civilisation of our own times but, as Professor Clifford Allbutt points out in his article on this subject, its prevalence throughout the world is an indication that it is no modern invention His description of the disease is ably supplemented by an account by Mr Victor Horsley of the traumatic variety which is so often of importance in medico-legal cases Mr Horsley very emphatically says that no case of traumatic neurasthenia "can be expected to end in recovery if the symptoms be severely marked unless treated by the Weir Mitchell method '

In editing the section on Mental Diseases Professor Clifford Allbutt has had the assistance of Dr G H Savage. All parts of this section are so good that it is somewhat difficult to select any portion for special commendation, but we may perhaps mention the article on Vice, Crime, and Insanity, by Dr C A Mercier Dr Leonard Guthrie's article on Night Terror Symptomatic and Idiopathic, with Associated Disorders in Children, is also very good

Sir John Batty Tuke's account of the General Treatment of the Insanities deserves to be specially mentioned Dr. J Milne Bramwell has contributed a description of the Use of Hypnotism in the Treatment of Insanity and Allied Disorders He considers that ' the question whether insanity in its graver forms can be cured by hypnotism must still be regarded as an open one Dr Bramwell has himself attempted to employ hypnotic suggestion in six cases of undoubted insanity, in five he failed to produce hypnosis, while in the sixth, although sleep was produced and the pain of an organic malady was relieved, yet the suggestions were entirely without effect upon delusions of persecution which had existed for many years.

Mr C T Dent has a short article on the Insanity which may Follow Operations and he points out that operational insanity must be distinguished from that due to the anæsthetic, the latter coming on at once, while in the former there is a clear interval The nature of the operation has little to do with the occurrence of the insanity, and although it occurs more commonly after operations of magnitude yet it has appeared even after tenotomy The treatment advised is to feed the patient well, at the same time, if drugs such as iodoform are being employed they should be discontinued

Almost half the book is occupied by an account of the Diseases of the Skin and this portion has been edited with the help of Dr J F Payne The subject has been divided among a large number of contributors Dr Colcott Fox deals with Erythema in its various forms and Urticaria, especially good being the account of Erythema Multiforme Dr, Payne has written the article on Eczema and in discussing the etiology he points out that traumatism must be considered an undoubted cause of eczema, for artificial dermatitis, which is first excited, is prone to be followed by the appearance of the same lesion in another limb, and no one could refuse to give the name "eczema" to the secondary eruption Dr Stephen Mackenzie is responsible for the account of Exfoliative Dermatitis and it is a most accurate reflex of the current opinion on this interesting disease

Dr H G Brooke has written the article on Psoriasis, and after an able and clear discussion of its etiology he tells us that he is inclined to believe that the neuro-vascular factor is primary, but that there is a secondary local bacterial cause which is essential to the full manifestations of the lesions A very good description of Herpes Zoster is supplied by Dr Henry Head, with an instructive chart which illustrates the age incidence of the disease but it would have been even more instructive if it had been constructed to show the frequency of the cases in proportion to persons living at the several ages, this could have been easily effected by the use of curved abscissæ The diagrams which illustrate the distribution of the various nerve roots are valuable, as the affected patches correspond to nerve roots and not to individual nerves

Dr J J Pringle has contributed the account of Ichthyosis, it is most carefully written, but we are inclined to dissent from the statement that cases appearing for the first time after childhood cannot be accepted as examples of ichthyosis

The only other articles which require to be mentioned are those on the Vegetable Parasites by Mr Malcolm Morris, on the Diseases of the Hair, by Dr H R Crocker, and on the Bacteria of the Skin by Dr J Galloway Mr Morris's paper is illustrated and a few other dermatological diagrams are given, but no attempt is made—and rightly, we think—to illustrate the diseases of the skin

An Appendix on Recent Progress in our Knowledge of Malaria concludes the volume The index contains references to the whole work, but is chiefly intended to refer the reader to the volume containing the information which he seeks; he should then consult the more detailed index of that volume

This as we have mentioned already, is the concluding instalment of this System of Medicine and in reviewing it we cannot refrain from speaking once more of the very high character of the work No such treatise on medicine has appeared since Reynolds's System and it may without danger of contradiction be said to be a worthy exposition of the present state of medicine in the United Kingdom

---

The Myology of the Pelvic Floor A Contribution to Human and Comparative Anatomy By PETER THOMPSON, M D Vict, Senior Demonstrator of Anatomy in the Owens College, Manchester London McCorquodale and Co 1899 Pp 108 *Price 5s*

THIS excellent work on the muscles of the pelvic floor is illustrated by 24 figures taken, not only from the human subject but from dissections on monotremes, marsupials, edentates, ungulates, rodents carnivores, insectivores, cheiroptera, and primates, so that it is a most valuable addition to our few detailed works on the development and morphology of the pelvic human structures. There is a well-marked difference between the pelvic floor of most mammals and that of the human subject In the former the weight of the abdominal viscera is largely borne by the ventral wall of the abdomen, whilst in man this weight is *sustained mainly by the floor of the pelvis owing to* the erect posture compelling special modifications which are unnecessary in animals in which the long axis of the body is horizontal. In mammals generally the pelvic floor is mainly muscular and is specially arranged for closing the clefts through which the rectal and genito-urinary canals pass, and is but little adapted for the support of weight, but as the body becomes absolutely or approximately vertical a distinct muscular pelvic diaphragm is developed in addition to the fibres controlling the clefts for the viscera. These layers are not only functionally but morphologically different in their development. The muscles of the "pelvic diaphragm" in man and the anthropoid apes are derived from the flexors and abductors of the caudal extremity of the vertebral column passing forward in a horseshoe shape to the pubes and encircling the rectum posteriorly. As the upright posture is assumed the number of caudal vertebræ diminishes and the muscles are thus adaptable for other functions. The sphincter muscles are derived from the sphincter cloacæ, and in man they are developed into two layers, one of which includes the superficial perineal muscles and the other those between the layers of the triangular ligament. The superficial perineal muscles are the sphincter ani externus, the transversus perinæi superficialis, the bulbo-cavernosus, and the ischio-cavernosus, whilst the deep-set include the constrictor urethræ, the transversus perinæi profundus, and the ischio-pubicus. The pelvic diaphragm is formed by the coccygei and levatores ani. These muscles are all thoroughly described and most clearly depicted in Dr. Thompson's monograph. We have read with pleasure this admirable piece of work in what is now in Great Britain almost a deserted scientific field and we wish that there were more workers on similar lines. The book is well got up and capitally illustrated.

Cure Prompte et Radicale de la Syphilis. Par le Dr. J. F. LARRIEN. (*Prompt and Radical Cure of Syphilis.* By Dr J F. LARRIEN.) Paris: Société d'Editions Scientifiques. Pp. 131. 1899. Price 4 francs.

THE author of this brochure objects to the use of mercury but not intemperately so. He holds that mercury is injurious when administered internally, as far as the actual cure of the disease is concerned, although he admits its power of suppressing or temporarily removing secondary manifestations He uses it externally to save time, either in the form of sublimate baths when the eruption is extensive or applied locally to skin lesions in the form of three parts of white precipitate to 30 of glycerine of starch, or he may use a gargle or mouth-wash of 1 in 10,000. In severe cases with eye or other threatening symptoms he uses mercurial inunctions for from five to 10 days as the treatment on which he usually relies is *not sufficiently rapid in its action for such cases.* This is as follows, whatever may be the stage or duration of the disease. *He gives every morning a quarter of an hour before breakfast* in a little sugared water three minims of tincture of iodine of recent preparation and a tablespoonful of a solution of iodide of sodium in distilled water containing 15 grains in each dose. This is taken for from 15 to 20 days in each month for from five to eight months. On the remaining days of each month no medicine is given, except in malignant forms when he gives tonics He never exceeds the specified dose, for although sometimes the immediate result may be better it is never lasting. General hygienic measures and judicious hydrotherapy may be simultaneously employed.

The author maintains that there are no contra indications for this treatment, and that it is especially good in the prodromic period, when symptoms disappear in three days, and it prevents secondary eruptions. If roseola is already present it is effaced in three or four days; general papular eruptions and condylomata disappear under local mercurial applications in from three to eight days. Continuing the internal treatment the manifestations are reduced to a few mucous plaques which may recur for from three to six months and that will be all. The treatment should be prolonged for two months after the disappearance of symptoms which in a previously healthy subject would have lasted for from six to eight months; even in chronic alcoholics treatment is rarely required *for more than a year. For cases in which no* treatment has been adopted for a long time or where mercury has been given, (!) it is prudent to give the iodine treatment for two or three months in the second year. Even palmar psoriasis and recurrent tongue erosions will not resist this iodine treatment, which is also excellent for the anæmia of the early stage.

The author brings forward many quotations, arguments, and cases in support of his propositions, and since those who have had the most extensive experience will have to admit that while it is generally easy to remove the symptoms of syphilis in many cases the most experienced practitioners fail to procure a definite immunity from their recurrence, it is worth while to test the author's method, without prejudice, as there is nothing irrational in the plan itself, the most prejudicial statement being that it is *always* successful.

LIBRARY TABLE.

The Pharmacopœia of Guy's Hospital. Compiled by the Committee of the Staff. London: H. H. G. Grattan. 1899. Pp. 222—It has been the custom to publish the Guy's Hospital Pharmacopœia since 1791, but obviously from that time onward a great number of changes have been made. The present little work, the size of which makes it suitable as a pocket-book, represents the ninth issue. To make the book more useful to students the present edition includes the British Pharmacopœia of 1898 so far as it is necessary to be known for the purpose of prescribing. Useful chapters have been added on the preparation of invalid foods, clinical tests, poisons, antidotes, and treatment This little work has been published at an opportune time and its contents will be consulted with advantage.

Merck's Manual of the Materia Medica. Darmstadt: E. Merck. 1899. Pp. 236.—Free copies of this manual may be had on application by medical men to 16, Jewry-street, London, E C. It forms a very useful pocket-book of reference and contains a terse account of drugs, including synthetics and other remedies which have recently been introduced in great number. It contains a summary of therapeutic indications in addition and a classification of medicaments. It has evidently been compiled with considerable trouble and care so as to form a reliable guide to the practitioner in regard more particularly to modern chemicals and drugs.

Aids to the Analysis of Food and Drugs. By T. H. PEARMAIN and C G. MOOR, M.A., F.C.S., F.I.C. Second edition. London: Baillière, Tindall, and Cox. 1899.—This little work is useful as an accurate guide for rapid work in connexion with the analysis of samples taken under the Food and Drugs Act. It is to the analyst what, so to speak, the "aid" book is to the student contemplating examination. The processes described are evidently based on the authors' experiences and should be easily followed from the clearness of the details given. A chapter is added on the Analysis of Urine which is followed by a few notes on the British Pharmacopœia, 1898. For the methods of simple analysis of foods with the view to the detection of adulteration the book may be consulted with confidence, but for more extended inquiry more advanced works would be necessary.

Synopsis of the British Pharmacopœia, 1898. Compiled by H. WIPPELL GADD, M.P.S., with Analytical Notes and Suggested Standards by C. G. MOOR, M.A., F.I.C. Fourth edition. London: Baillière, Tindall, and Cox. 1899. Pp. 223. Price 1*s.*—This little book is crowded with information of value to the pharmacist and the information is easily found since it mostly occurs in tabulated form. An important addition is that contributed by Mr. Moor on Analytical Notes and Suggested Standards. The latter would seem to require further consideration before being adopted. This synopsis is an excellent *vade mecum* for the pharmacist.

A Handbook of Nursing. By M. N. OXFORD. London: Methuen and Co. 1900. Pp. 283. Price 3*s.* 6*d.*—Miss Oxford is the Sister of a ward at Guy's Hospital, and therefore she possesses the great qualification of having a thorough knowledge of the subject about which she is writing. We gather from the preface, however, that portions of the book are attributable to those members of the staff who lecture to the probationers upon medicine and surgery. The book is divided into three parts. Part I. deals with introductory matters and general nursing instructions, Part II. is devoted to surgical nursing methods, and Part III. to the nursing and care of medical cases. Besides these there are useful appendices, notably one upon the nursing of infectious cases and another upon the feeding of children. The book is very plainly and simply written, and apart from its use to nurses we should say it would also be of use to young practitioners who have just left a hospital and are going into private practice either on their own account or as assistants. A man who has been a house surgeon or house physician will find when he goes into private practice that he feels the want of his dressers or clerks and of the sister and nurses of the ward. He will no longer be able just to write down, "Hot bath," or to say casually, "He may have ten drops," but in many cases he will have to arrange for these matters himself. He will have to cut his dressings himself or even to pad splints with his own hands, or at any rate show someone how to do it, and he will have to give directions for the prevention of sore backs. Useful hints on these matters are given in Miss Oxford's book. The publishers deserve praise for the type and, above all, for the paper which is of a good colour and free from clay, so that instead of the book being cumbrously heavy, as so many modern books are, it is light and pleasant to hold.

Aseptic Surgery. By CHARLES BARRETT LOCKWOOD, F.R.C.S. Eng., Assistant Surgeon to, and Lecturer on Descriptive and Surgical Anatomy at, St. Bartholomew's Hospital. Second edition. Edinburgh and London: Young J. Pentland. 1899. Crown 8vo Pp. 264. Price 4*s.*—The second edition of this useful handbook to asepsis in surgery differs but little from the first, which we reviewed in THE LANCET of July 11th, 1896 (p. 117). It is a trustworthy guide to the practice of asepsis and may be employed with confidence by anyone who wishes to understand the principles by which the modern surgeon is guided. The instructions are clear and trustworthy, and though exception might be taken to one or two statements yet there is nothing that prevents us from recommending it as the most simple yet exact treatise on the subject.

Golden Rules of Physiology No. VI. "Golden Rule" Series. By I. WALKER HALL, M.B., Ch B Vict., and J. ACWORTH MENZIES, M D., C M. Edin Bristol: John Wright and Co.; London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1900. Pp. 80. Price 1*s.*—We have upon previous occasions expressed a favourable opinion of the "Golden Rule" Series, and this, the latest of the series shows no falling off from its predecessors. The rules are very clearly and shortly set out, so that the book should certainly attain to the object of the authors, as expressed in the preface—namely, that for those who have read text books and are on the threshold of an examination it should be a stimulant to memory and thought. The subjects are purposely arranged in an unsystematic way, physiologically that is to say, but they are arranged alphabetically, so that they are easy of access. In the Chemistry section we feel inclined to add one caution to those set out by the authors—namely, "Don't do colour reactions by artificial light, except it be that from a Welsbach burner." From our own experience this caution is not unnecessary.

The British Almanac for 1900. London: Published for the Stationers' Company by Charles Letts and Co. Price 1*s.*—*The British Almanac* certainly has a marvellous quantity of information, useful and otherwise, contained within its pages. So good is most of the information that we should have thought the publication was quite able to stand upon its own merits without appealing to the public by giving away presentation coupons for corsets and headache powders. A portion of the book to which we most strongly object is "The Family Doctor," by Dr. E. P. Philpots, M.D., F.R.G.S. Under the heading Useful Notes for Emergencies Dr. Philpots gives a variety of details which if they are intended for non-professional persons may be productive of infinite harm and if for his professional brethren are quite unnecessary. The "useful notes" are loosely written. For instance, under the heading "Burns and Scalds" we read: "If patient collapse give 25 drops of laudanum with some warm brandy and water internally." By far the greater number of cases of burning in families occur in children and 25 drops of laudanum is, to put it mildly, a large dose for a child. The treatment might prove fatal. Again, the paragraph entitled "Eyes, Foreign Bodies in," gives the following instructions: "If, however, the foreign body is embedded in the front of the eye (the *cornea*) it must be 'dug out' with a needle." Now, every medical man knows this, but the medical profession is not addressed in the *British Almanac*. When the anxious mother or father of a family begins to dig out foreign bodies with a needle disaster will soon follow. We hope that this section will be expunged in next year's issue.

Dod's Parliamentary Companion, 1900. London: Whittaker and Co. Price 4*s.* 6*d.*—This invaluable little compilation is brought up to Jan. 5th of the current year. The House of Lords is, as we all know, graced by the presence of one medical peer—namely, Lord Lister. There were eight medical men sitting in the House of Commons on the publication of the *Parliamentary Companion*—namely, Sir Charles Cameron, Dr. Farquharson, Sir Walter Foster, Dr. MacDonnell, Sir W. Priestley, Dr. Tanner, Sir R Finlay, and Mr. J. F. Fox, who is F.R.C.P. and S. of Kingston, Canada. Sir R. Finlay left the practice of medicine for that of law. The number of medical Members of the House of Commons is now increased to nine by the election for London University of Sir Michael Foster.

VACCINATION AT WARMLEY.—At the meeting of the Warmley (Gloucestershire) Board of Guardians held on Feb. 6th it was reported that the births of 451 children had been registered during the first half-year of 1899; of these, 158 had been successfully vaccinated, certificates of conscientious objection were granted for 22 and certificates for postponement for five, 55 died, four were removed, and 207 were unaccounted for. One of the guardians remarked on the large number unaccounted for and proposed a motion, which was carried, drawing the attention of the vaccination officer to the fact.

# Analytical Records
FROM
THE LANCET LABORATORY.

MALTED MARMALADE.

(James Keiller and Son, Limited, Dundee, Tay Wharf, Silvertown, London, E)

THE presence of the active starch-digesting principle of malt in marmalade affords a distinct dietetic gain. Further, it adds very pleasantly to the flavour of this preserve. The marmalade is evidently prepared with care and with good materials, and according to our experiments it rapidly digests starchy substances. In appearance the preparation differs in no particular from ordinary marmalade. The combination is an excellent one, the malt adding very materially to its nutrient value while the bitter principles of the orange have a favourable effect on gastric action. The marmalade is concentrated at a comparatively low temperature in vacuo so as to avoid the destruction of diastase.

AMYLOFORM.

(Thomas Christy and Co, 25, Lime street, London, E C)

Amyloform is a white, somewhat gritty powder containing, as its name would suggest, formaldehyde and starch. It is a definite chemical combination which is said to decompose in the living animal organism with liberation of formaldehyde and starch. The former constituent is available for antiseptic treatment and the latter is hydrolised and absorbed. The powder is odourless and resists being disrupted at a temperature of 180° C. This fact has suggested its suitability for impregnating gauze for the treatment of wounds. We found that amyloform was insoluble in most ordinary solvents but that on heating with dilute potash solution it gelatinised and turned yellow. It reduces Fehling solution slowly and iodine strikes the blue colour characteristic of starch. It would seem to possess many advantages as a general antiseptic used both internally and externally.

KEYSTONE BURGUNDY (FERRUGINOUS).

(Stephen Smith and Co, Limited, Malmesbury-road, Bow, London, E)

Our analysis of this wine gave the following results: Extractives, 4 00 per cent.; mineral matter, 0 44 per cent.; alcohol, by weight 13 15 per cent., by volume 16 24 per cent., equal to proof spirit 28 46 per cent; tartaric acid, 0 43 per cent.; volatile acid reckoned as acetic, 0 09 per cent. It is a somewhat full-bodied wine possessing the generous qualities of a good burgundy. It is practically free from volatile acid, a fact which speaks of its sound condition. The mineral matter contained a notable amount of iron. Though the wine is of a robust type it is free from that roughness of flavour commonly present in wines of its class.

SPECIAL DRUGS (MERRELL).

The W. S Merrell Chemical Co, Cincinnati; 47, Wilson street, Finsbury-square, London.)

Amongst the specimens submitted to us for inspection by these manufacturing chemists may be mentioned as possessing special interest the preparations "ferro salicylata" and "bismuth hydrastia" respectively. The former is a combination of methyl salicylate and tincture of the citro-chloride of iron. It is said to give excellent results in the treatment of rheumatism being, besides anti-rheumatic, antiseptic and tonic. The solution of bismuth hydrastia consists of the double citrate of bismuth and hydrastia. It is a colourless solution and slightly viscid. It has been used in the treatment of irritable, inflammatory, or ulcerated conditions of the mucous surfaces, in diseases of the stomach and bowels, and locally in diseases of the nasal passages, the eye, the throat, and the urinary organs. In addition to the foregoing drugs we have examined a sample of fluid hydrastis which is prepared without alcohol and which forms with water, alcohol, or glycerine a clear solution. During the process the objectionable resin found in the hydrastis is rejected. Lastly, the specimens included salicylic acid prepared from oil of wintergreen and the sodium salt.

"I AND I" FOOD.

(The Infant and Invalid Food Co, Limited, Cereal-buildings, 54, City-road, London, E C.)

The analysis of this food was as follows:—Carbohydrates, 75·50 per cent.; proteids, 13 00 per cent.; fat, 3 30 per cent; mineral matter, 1·40 per cent.; moisture, 6 80. It will be noted that the preparation contains the three important classes of food material—heat-producing, flesh-forming, and bone-producing—in desirable ratio. The proportion of proteids and fat is especially commendable. Further, the method adopted for the preparation of this food is calculated to render it easily digestible.

KOLA ASTIER

(Wilcox and Co., 83, Mortimer street, Great Portland street, London, W.)

The pharmacology of the kola-nut is now well known. It contains certain principles, amongst which are caffeine, theobromine, kola red, &c, which are decided nerve stimulants. Kola astier occurs in the form of a granulated powder with a cocoa-like colour. It readily yields crystals of caffeine on extraction with chloroform. Each teaspoonful is said to contain two grains of caffeine. Whilst admitting the value of this preparation as a nerve stimulant and as excellent for the purpose of relieving languor and fatigue we would point out that it should not be used indiscriminately but under the direction of the physician. Caffeine is not without dangers when administered in large doses and for a length of time.

BAKING FLOUR FOR MAKING BROWN BREAD.

(The Cereals Co, Limited, Greenock.)

We found no striking novelty in this flour. It produces a good loaf of good wheaten flavour and possessing satisfactory texture. The amount of proteids found was disappointing, the figures we obtained being 9 00 per cent. The mineral matter containing phosphates was proportionally high and amounted to 1·99 per cent. The moisture was 13 37 per cent. The flour contained fragments of indigestible husk.

REEVE'S COCOA ESSENCE.

(The Sweetmeat Automatic Delivery Co, Limited, 104, Baltic-street, Bridgeton, Glasgow)

On examination this proved to be a cocoa of excellent quality with the greater part of the indigestible cocoa fat removed. It contains 4·30 per cent. of moisture and ·20 per cent. of fat. The mineral matter amounted to 5·5 per cent. and exhibited a soluble alkalinity equivalent to 0 8 per cent of potash. The cocoa is satisfactorily "soluble" and has evidently been rendered so by a special departure in manufacture. As we have before shown raw cocoa requires careful preparation in order to be "soluble" in the cup, leaving as little sediment as possible. This process, too, increases its digestibility and therefore its suitability for invalid use.

FLUID EXTRACT OF MALT AND GLYCEROPHOSPHATES.

(Duncan Flockhart and Co, 104, 106, South Canongate, Edinburgh)

This preparation is a decided therapeutic improvement upon the ordinary syrup of glycerophosphates, for it combines the advantages of the salts with the well-known digestive and nutritive properties of extract of malt. It further contains the nerve stimulant caffeine in a stable form in the place of the kola which was suggested in the original formula of Dr. Robin (of Paris) The preparation is valuable where an improved general nutrition of the nervous system is indicated. Experience has shown that the glycerophosphates are very advantageous under these conditions and their administration with active essence of malt is calculated to add to their therapeutic value in this respect. Each fluid drachm of the extract of malt contains the glycerophosphates in the following quantities: calcium 1 gr., sodium ½ gr., potassium ½ gr., manganese ⅛ gr., iron ¼ gr., with ⅛ gr. of caffeine.

TABLE JELLIES

(TOUZEAU PARRIS AND CO., LIMITED, ENFIELD WORKS, MILL HILL PARK, ACTON, LONDON, W.)

Whatever process is adopted for the production of these jellies it is evident that the best materials are used and that care is taken to avoid all contaminating influences. We could find on careful examination no objectionable colouring matters or preservatives or metallic impurity. The jellies are said to be made in silver-lined pans and consist of attractive and almost transparent unshrinking gelatinous slabs possessing a delicate odour of the various fruits employed. They yield an excellent table jelly by simply stewing in hot water and allowing the liquid to cool. In particular the jellies may be commended for their excellent yet delicate flavour, which is successfully derived from the fruit and preserved by a special process. We believe these preparations are honestly described as containing natural fruit flavours. Jellies occupy a not unimportant place in dietetics. They are pleasant to partake of, nourishing and attractive, and afford often a grateful adjunct to the food of the invalid.

BAKING POWDER.

(H. K. BUSHELL, 343, OXFORD-ROAD, READING.)

We could find no novel feature in the composition of this powder. It is, at any rate, free from objectionable constituents such as alum. It contains starch and the materials commonly employed for effecting effervescence. It serves as a convenient aerator for "raising" bread, and containing nothing but innocent materials is quite unobjectionable for the purpose.

"MAFUTA" PRESERVED BANANAS

(THE MONTPELIER FRUIT AGENCY, 119, MIDDLESEX-STREET, BISHOPSGATE STREET, LONDON, E.C.)

The fruit is preserved by simply extracting the water from it, and in this way it is analogous to the dried fig. Preserved bananas are somewhat mawkish to the taste. Nevertheless, they deserve a place in the dietary considering how really nutritious this fruit is. For some reason not yet explained the starch of the banana is much more readily digestible than are the cereal starches, besides which the fruit contains a notable proportion of nitrogenous material. We could find no objectionable preservatives. The fresh fruit can so readily be obtained in this country in excellent condition that there hardly appears to be a reason for providing it in the preserved state. There is, however, a curious but not disagreeable flavour in the preserved banana, suggesting slight fermentative change and not unlike the flavour of the spirit obtained from the fermentation of molasses.

PATENT CUSTARDS.

(S. CHIVERS AND SONS, HISTON, CAMBRIDGE.)

According to our examination the composition of these custard powders is quite simple and the materials are free from reproach. By simply boiling with milk and allowing to cool a custard is obtained. Of course the nourishing property of a custard prepared in this way cannot be compared with that of the true custard prepared with eggs. Indeed, the "Patent Custards" contain relatively a very small proportion of proteid matters.

New Inventions.

AN IMPROVED STORAGE BATTERY, "RESISTANCE," AND CHARGING BOARD FOR MEDICAL USE.

WE have recently inspected some interesting electrical apparatus for medical and surgical use which present features of advantage to the practitioner and surgeon. Thus in the battery the chances of short circuiting happening are reduced to a minimum by introducing a highly porous medium between the plates. The battery, in fact, is almost of solid mechanical construction. The separating medium is of such a highly porous nature that it offers practically no resistance, and, indeed, it is said that a standard cell which has a capacity of 30 ampères at its normal discharging rate (that is to say, three ampères) can be discharged at three or four times its normal discharging rate without a serious fall of pressure or without deterioration of the plate. The positive material, being covered by the separator, cannot disintegrate, while elastic bands are provided which hold the elements together and compensate for any expansion or contraction which may occur either during the forming or charging and discharging operations. The metal containing frame for the active material is so arranged that all portions of the material are in intimate contact with it; therefore the whole mass of the material is put into service. In this way a very large capacity for a given quantity of active material is obtained. The makers, indeed, state that they obtain at normal rates of discharge a capacity of one and a quarter ampère hours per ounce of lead peroxide—a result, they believe, which has not been obtained in any other form of lead storage battery. The battery is specially constructed to withstand a considerable amount of rough treatment and the connexions between cell and cell are accessible so that should a disconnexion occur it can be easily remedied. This battery has given excellent results for x-ray work and is very well adapted for carriage lighting. The same electrical engineers have introduced a variable compression resistance which medical men will find highly convenient for regulating the intensity of the light of any of the lamps which they may have in use. Its range being very large renders it equally useful for working lamps, small cautery instruments, or induction coils. In the case of small cautery instruments the heat can be regulated to a nicety, as a variation in pressure of a fractional part of a volt makes a considerable difference in the heating of platinum wire. Thus the finest possible adjustment can be effected by this new instrument. By an ingenious arrangement a large radiating surface is presented, the resistance discs being kept apart by springy metal plates which give elasticity and a correspondingly large radiating surface. A valuable adjunct to this equipment is a special charging board which enables anyone having a direct current circuit available to re-charge his battery without the possibility of joining it up wrongly. By means of a little needle actuated by a magnet the positive pole is at once indicated and no mistake can be made. The device is a great improvement upon pole finding paper. The designers of the apparatus described are Messrs. Niblett, Sutherland, and Marcuson, electrical engineers, of 61, Chandos street, Strand, W.C.

THE NITRO-PROPIOL TEST FOR SUGAR IN URINE.

Advantage has recently been taken of the fact that nitro-propiol interacts with glucose *to form indigo, in connexion* with a simple and ready test for sugar in urine. Nitro-propiol is, to give it its complete chemical name, the sodium salt of ortho-nitrophenyl-propiolic acid $C_8H_4(NO_2)C : CCO_2H$, so that the reaction taking place may be thus represented: $2C_8H_4(NO_2)C \quad COO_2H + 4H = C_{16}H_{10}N_2O_2 + 2CO_2 + 2H_2O$. The change of course is due to the reduction of the nitro-propiol *by the glucose*. It is *stated that the test* is not affected by kreatinine, glycuronic acid, or other constituents of the urine or by such drugs as iodine, salicylic acid, turpentine, &c., which may occur in the urine. The test is stated to indicate with certainty 0.05 per cent. of grape sugar. Nitro-propiol is supplied in tablets ready for use, and in order to carry out the test one tablet is dissolved in three drachms of water after which 10 drops of the urine are added and the mixture is then gently boiled for from three to five minutes. Indigo blue soon appears if sugar be present and the quantity of the precipitate or the intensity of the colour is proportional to the amount of glucose present. The test is known as Teusch's Nitro-propiol Test and the tablets are supplied by Messrs. Wilcox and Co., of 83, Mortimer-street, Great Portland-street, W.

THE laryngoscope devised by Dr. Mark Paunz, described and figured in THE LANCET of [illegible] 27, is made by Messrs. S. Garay [illegible] Budapest.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 17, 1900.

IN another column there will be found the full text of the Midwives Bill, which was introduced into the House of Commons by Mr. TATTON EGERTON on Friday, Feb. 2nd. As will be seen the differences between it and the measure introduced into the House in January, 1899, are very slight and consist mainly of a few additions made at the suggestion of the Privy Council. It will be noticed also that throughout the Bill the *words "certificate" and "licence," "certification" and* "licensing," have been transposed, so that the certificate now admits to the roll while the licence is an annual affair granted by the local supervising authority. The Bill has obtained the second place for Wednesday, Feb. 28th, and will then be read for the second time unless the debate on the measure which has obtained the first place on the same day be unexpectedly prolonged. Under these circumstances it seems to us imperative that the medical profession should make up their minds what course they desire Parliament to pursue. The "Midwives Question" is, as we have frankly recognised and often said in these columns, an exceedingly difficult one to solve. For both those who do and those who do not desire legislation for the regulation of the practice of midwives—whether it take the form of Mr. TATTON EGERTON'S Bill or of some similar measure—can with equal force maintain that their opinion is the right opinion on humanitarian grounds and no less on medical grounds. To leave the people to the mercies of the Gamps is cruel, but to supply them with a semi educated grade of medical attendants is no kindness. If the first course leads to disasters, the second would seem as inevitably to make for tragedies However, we are not now discussing the question at large or any Bill in particular. We are only urging on the profession that there is no time to be lost if their voice is to be heard on one side or the other. We do not say that Parliament will adopt the attitude that it is desired to take by the medical profession, for Parliament nowadays is especially and rightly opposed to legislation in favour of classes; but we are certain that it will be of immense assistance to our law-givers if they can know what is the view of the medical profession. For this view by all tradition should be a liberal one and instinct with a desire to better the condition of the sick poor. We have decided to make an attempt to ascertain what is the general feeling of those medical practitioners whom the proposed legislation concerns. The Bill does not contemplate Scotland or Ireland in its working. To the English medical men we have addressed a circular letter begging them to tell us if they are in favour of legislation for the regulation of the practice of midwives or not, and, further, if they are in favour of such regulation, whether the Bill now before the House meets with their approval. We hesitate to say that the medical practitioner who does not answer our circular is convicted thereby of indifference to the whole question, for it seems to us that to do so would be tantamount to making a rather too positive demand for a reply. But we do say that the "Midwives Question" is an exceedingly important one; that such circular letters are not issued in thousands without the expenditure of time, trouble, and money on our part; and that to write a word or two upon a postcard already stamped and addressed, and to place that postcard in the post should not be a very onerous task for anyone. We trust that we shall receive answers generally and promptly to the circular, for whether Parliament is swayed or not entirely by the opinion of the medical profession, that opinion cannot be without great influence and ought to be registered.

◆

THE Managers of the Metropolitan Asylums Board at their last fortnightly meeting found themselves confronted with a choice between two evils. The matron of one of the hospitals of the Board had written stating that she had been selected as a nursing sister for a military hospital at Cape Town (which presumably means that she had voluntarily offered herself and had been accepted) and she asked to be granted leave of absence without pay during the time that her services were required by the Government. The Board therefore had to choose whether they would permit one of their institutions to suffer such disorganisation as might be expected to arise from the appointment as a temporary matron of one who would know that she occupied her position for a wholly indefinite period which no efficiency or energy on her part would prolong, or whether they would boldly incur such unpopularity as might be expected to result from a decision which would strike the thoughtless as unpatriotic. The Hospital Committee recommended that the matron should be informed that the Managers could not see their way to accede to her request, and the chairman of the committee brought forward a motion embodying this recommendation, which was duly seconded and supported. On the other hand an amendment was moved to the effect that the matron's application should be granted. A lengthy discussion took place, in which the views of both sides were urged with considerable force and with some warmth. It was said on behalf of the Hospital Committee's recommendation that although leave had been granted to humbler officials and no difficulty had been found in providing for the performance of their duties during their absence, to place a hospital in complete charge of a substitute was another matter. However great the national needs might be, still nothing had yet happened to the country and nothing ever could happen which would justify the Board in neglecting the needs of the sick under their care. For the counter proposal that the matron should be allowed to go, and in due course to return, it was urged in strong terms that to refuse her request would show an unpatriotic spirit. The Board was called upon to emulate the loyalty which had animated every other body in the country. In the end the motion recommended by the Hospital Committee was carried, so was a second one naturally resulting from the , that the Board should accept the matron's resigna of her position This she had tendered in a further er, being apparently aware that her first application ld not be favourably received, and having made up her d in any case to proceed to South Africa

ith the matron's decision we find no fault She may de e considerable credit for the course which she has taken voluntarily abandons a comfortable if responsible and lions, post for one which must imply arduous work in y trying circumstances At the same time we cannot sympathise with the Board in the situation in which y found themselves placed and we commend their ision which showed that they fully appreciated their position in the matter and were determined rageously to maintain it That it would be attacked was ain A contemporary, a leading London daily newspaper, assailing the Metropolitan Asylums Board quotes the ing of the Saviour of mankind, "The poor ye have always h you" Without going into the circumstances in which se words were spoken we hold that to interpret them a command to neglect our sick poor at home while ending to our wounded soldiers abroad is both wholly trary to their spirit and to the spirit of Him who ke The present war has evoked an extraordinary amount zeal on the part of thousands who have voluntarily red *themselves to take part in it and of self sacrifice* the part of those who have *undertaken to keep* open the ces of the volunteers until their return Many have gone cheerfully because their duties as reservists compelled m to do so and these also their masters have in almost ry case undertaken to employ again There is, how r, an obvious distinction between the reservist and the unteer, just as there are limits beyond which volunteering active service is strongly to be deprecated Soldiering essentially for the young, the active and the specially ined, the middle aged those accustomed to sedentary es and without military experience, are likely to become rdens to their fellows at the front Again, those whose aces cannot be filled if they fall—fathers of families, for amples who leave wives and children unprovided for—ese should not put themselves forward to go As a rule, ose who have volunteered are young men who have not ven hostages to fortune and whose duties can be dis arged by others; we doubt if employers would be ready to cilitate the departure of the more responsible of their rvants, to put temporary substitutes into the places of con lential clerks and trusted managers, nor can they reason ly be expected to do so For similar reasons those cupying such posts cannot reasonably or rightly abandon em of their own free will—impelled, as they are no oubt largely by patriotism but also by a Briton's love of lventure—and expect *their billets to be temporarily filled* he loss should anything go wrong during their absence ould fall upon their employers and the business of the ountry must go on despite the war

The Metropolitan Asylums Board clearly took this view f their matron's application They expressly said that hey had allowed minor officials to go with the promise hat they should return, but that they could not permit he smooth working of one of their hospitals to be impaired in order that the official responsible for it should do for her country what others might undertake without causing loss to anybody The position of the Board, moreover, differs in an essential particular from that of the commercial employer to which we have compared it and makes the course which the Board have taken more clearly the right one The Board might incur trouble in finding a temporary matron, but any loss resulting would not fall upon themselves but would be felt by those persons who are the inmates of the hospitals of the Board and with the safeguarding of whose interests the Board are entrusted The Board if they had granted the request of the matron to the possible injury, in however slight a degree of those entrusted to their care would have exhibited a cheap patriotism, and have been guilty of a genuine breach of trust

---

A STATE of war sets in exhibition the most contradictory sides of humanity If it seems to expose the worst aspects of our nature it also undeniably brings into view some of the best Among the more active participants it is the cause of self sacrifice, self denial, and cheerfulness under the most trying circumstances in a determination to do all that lies in the power of each for his Sovereign and country And if we who stop at home cannot do so much yet we recognise that it is our part to minimise as far as we can the sorrows and distresses which war inevitably brings in its train The present conflict in which we are engaged has given many examples of a wish, and of more than a wish to help Neither has this desire been confined to one class or one corner of the empire Relief funds abound and subscriptions have been sent not only from the United Kingdom, but from every part of the QUEEN'S realms Every class of woman, from the highest to the lowest, has vied in making articles of clothing for the troops or in providing them with comforts wherewith to lighten the hardships of the campaign

But there is a class which is in danger of being neglected —or perhaps we should say overlooked—and that is the class comprising those officers who are not too well off in the matter of temporal goods We recently published an appeal from the Duke of ABERCORN[1] "on behalf of those sick and wounded officers of all services whose means are inadequate to secure that efficient medical and surgical treatment which will often be needed to restore to them, after their return home the health they have sacrificed in the service of their country His Grace went on to point out that there would certainly be many officers who had small private means and who would not be in a position to command the skilled assistance which they would most urgently need He therefore felt that an attempt should be made to offer assistance It will be remembered that an influential committee was at once formed and already a fair amount of money has come in through subscriptions It will be difficult, perhaps to distribute the benefits of this fund in a way which will be at once unostentatious and calculated to do the most amount of good But the possible recipients will not hesitate to take their share if the help is offered to them, as we are sure it will be, as an expression of earnest desire to show gratitude to those who have done their best for their country. Sickness is always a heavy tax upon the resources of even a rich household, and in the ordinary English home it involves disturbances of the domestic *régime* which militate much against the recovery of the patient. The regimental and professional demands upon the purse of an officer absorb much of his pay, and for anyone whose private means are somewhat straitened the thought that every extra sum spent upon himself means less comforts, we might say less necessaries, for his wife and children is a factor calculated to retard restoration to health. Therefore it is that we welcome the appearance of the fund in question. The patients will for the most part pay some share of the expenses, and there should be no hesitation in accepting their offer to do so. Secondly, as regards the medical or surgical attendance it is necessary that the medical man should receive some fee. Many leaders of the medical profession have joined the committee and there will be no lack of consultants ready to give their services; but this is not what is wanted. If one operating surgeon is thus profuse in doing good others will feel bound to follow suit, and we should soon reach the position of the poor officer being helped by a surgeon but little if any richer than himself. By all means let operations be charged at a great reduction from the usual fee; towards the reduced fee the patient should contribute a quota such as his means can afford, while the balance could be made up from the fund, which should also supply dressings and bandages if such are needed.

---

[1] THE LANCET, Jan. 13th p. 133

It is above all things necessary to make the recipients understand that help is offered ungrudgingly, unostentatiously, and with a real desire to repay benefits already received. Aid will not only help themselves but those dear to them. It is hard to fight, hard to see companions falling on every hand, but harder still is it for those who have to stay inactive at home. Hear the words of one unjustly called a cynic: "Dreadful doubt and anguish—prayers and fears and griefs unspeakable—followed the regiment. It was the woman's tribute to the war. It taxes both alike and takes the blood of the men and the tears of the women." Let us see to it that additional sorrow is not laid upon both those who fight and those who suffer in silence by any lack of skilled aid which may help to restore him who has unselfishly given his best. We hope that our readers will contribute to the medical fund in aid of the sick and wounded officers and will bring the fund also to the notice of their friends and patients.

THE electors of the University of London, in choosing a successor to Sir JOHN LUBBOCK, have made a good selection. They have chosen one of the most distinguished graduates of their University, who has achieved an enormous reputation both as teacher and man of science in the sister University of Cambridge. The claims of Sir MICHAEL FOSTER have been so successfully vindicated by the electors, and are indeed so obvious, that it seems unnecessary to revert to the attempts that were made during the contest to show that as a Cambridge professor he must necessarily be out of sympathy with the external *student*, and therefore with the University of London. It shows to what straits Sir MICHAEL FOSTER'S opponents were driven to find arguments against him that such a plea should have been put forward. In his brief speech after the result of the election was announced the new Member of Parliament expressed his intention to do his duty by labouring in the House of Commons not for the interest of any particular class, "be they doctors or lawyers, men of letters, men of science, or men of business, internal or external students," but for the common good of all. He took no narrow view of the future of the University, but considered that in its new form it has before it a great future. Such hopefulness in the representative whose election coincides almost exactly with the reconstitution of the University is of good omen—especially when it is remembered that Sir MICHAEL FOSTER, who claims to owe everything to the University of London, has since played a conspicuous part in an ancient university founded and developed on very different lines. What is wanted in the present position of the University of London is the help of men who are in sympathy with all that is best in both old and modern universities, and who realise that the time is opportune for creating in this metropolis a university combining all the advantages of both and free from some of their trammels. Surely no one could have been chosen by the graduates to represent them in Parliament more likely to afford such help, or more free from prejudices, academic or theological, general or domestic, than Sir MICHAEL FOSTER. He is returned as a supporter of the Government upon one or two points which at present dominate public attention, but a man who rejoices in being born where CROMWELL was born may be expected to assert in Parliament the claims of truth regardless of party considerations.

The election of Sir MICHAEL FOSTER by a large majority is not only good for the interests of the University of London, but will do much to strengthen faith in the Parliamentary representation of universities. If the members of universities have no claim to special representation so much the worse for them. The universities have it in their power, and should have it in their disposition, to return men to Parliament of special usefulness who may never make a political speech, and who yet may be able to see what are the great wants of the country and to express them in terms all the more forcible because their words do not smack of the political caucus. On all these grounds we rejoice in the election of Sir MICHAEL FOSTER. The return of Dr. COLLINS to Parliament by an academic constituency, largely medical, would have been unfortunate for reasons which we considered it our duty to indicate clearly before the election, while Mr. BUSK'S candidature did not commend itself to us any more than it did to the constituency.

UNIVERSITY OF CAMBRIDGE.—Vacancies in the boards of electors to the several chairs in the department of medicine have been filled up as follows: Chair of Anatomy, Dr. D. MacAlister; Downing of Medicine, Sir T. Lauder Brunton; of Physiology, Dr. W. H. Gaskell; of Surgery, Mr. T. Holmes; of Pathology, Dr. L. Humphry.

Annotations.

"Ne quid nimis."

"PUNCH" AND THE CHILDREN.

CHILDREN of all ages take a delight in *Punch* and *Punch* has always made it a tradition in its genial pages to love the children even while recording examples of their "terribility." It is, therefore, not surprising to us to find an eloquent appeal issued from the *Punch* office on behalf of the Hospital for Sick Children, Great Ormond-street, W.C. We knew this hospital to be badly in want of money, but the proprietors of *Punch* state that "unless a very considerable sum is shortly forthcoming the hospital must inevitably close its doors this year." Messrs Bradbury and Agnew are making an effort to enlist the sympathy and obtain the material assistance of all people who would regard as a calamity the closing of this the oldest children's hospital in England. To which end they have in the current number of *Punch* published a special appeal together with a reprint of a story by Mr. Anstey Guthrie which appeared in *Punch* of Jan. 31st last. We can only in the strongest terms recommend our readers to do as they are asked by the proprietors of *Punch*—i e., to give what they can to a splendid charity and persuade as many people as possible to do the same. It is needless to insist upon the sufferings of sick children who reside in a poor home—every medical student who has been a few minutes in an out-patient department learns something of what these sufferings are The war, we know, has made great calls upon all purses, but there must be many among us who can still spare something for that house of mercy the Great Ormond-street Hospital. Donations will be thankfully received on behalf of the "Ormond-street Hospital Fund" by Messrs. Bradbury, Agnew, and Co., 10, Bouverie-street, Fleet-street, E.C., whom we congratulate upon their efforts.

"HALF A MAN" IN COURT.

A YOUTH from Jamaica, described as dark-skinned and beardless, sought the advice of Mr. Plowden at the Marylebone Police court a few days ago and told the following story. Owing to the ill treatment of his stepfather he had run away from home and joined a ship as an ordinary seaman He was, however, unable to do his work properly because, as he told the magistrate, the upper part of his body resembled that of a woman. The captain of the vessel discovering this fact put him on easier work, but absolutely refused on reaching Liverpool to re engage him, saying that he wanted a man and not half a man Since this he had failed to find work, and having wandered up to London in a destitute condition he applied to the court for help. No doubt this individual is an example of the abnormality known as gynæcomastia or gynæcomazia—a condition well recognised by all medical writers. It occurs in male animals as well as in man. Thus Aristotle records the case of a he-goat at Lemnos who furnished milk from which most excellent cheese was made The oracle on being consulted as to the nature of this prodigy predicted a great increase of fortune for the happy owner. According to Puech breasts of female type are found as often as 1 in every 13,000 conscripts. That the presence of well developed breasts does not necessarily interfere with the duties of a seaman is shown by the case recorded by Morgan[1] It is that of a man, aged 21 years, admitted to the Royal Naval Hospital at Hong-Kong, whose right mamma had the appearance of the well-developed breast of a full-grown woman. The areola was large and brown coloured, but the nipple was the same size as that on the left breast. The breast was first noticed to enlarge at 16½ years of age; since then it had steadily increased, but no milk had ever been present. The external genitalia were well and fully developed. The man complained of no discomfort except occasionally, when drilling aloft, his breast came in contact with the ropes. Hutchinson[2] records a very interesting case of a boy of 15 years of age, the son of a woman affected with acromegaly. He was enormously fat in all parts of the body but without a trace of hair on the face. His breasts were as large as those of a well-developed young woman and had fairly large nipples. The penis, scrotum, and testicles were extremely small, the latter not bigger than small acorns, while the pubic hair was almost absent. Such atrophy of the external genital organs is not infrequently associated with gynæcomastia. Not only are well developed breasts met with in males of all ages, but every now and then cases occur in which these individuals are able to suckle young infants. Gould Franklin, in his "Voyages to the Polar Seas," quotes the case of an old Chippewa Indian whose wife died in childbirth and who put his infant to his breast and prayed that milk might flow. It did so flow and he was fortunate enough eventually to rear the child. Possibly this is the same Indian, then a chief, 101 years old, whom Kane alludes to in his book upon the Indians of Hudson's Bay. Thomas Bartholin mentions the case of a man who had so much milk in his breast that he was accustomed to draw it off and make cheese of it which he sold "to the curious" If we are to believe the *Journal des Sages Femmes* a quack practitioner at one time started a school for male wet-nurses, holding out as an inducement to possible clients the great physical advantages their babies would be likely to derive from being suckled by sturdy men. The development of breasts in the male with or without the presence of milk is not uncommonly hereditary, and histories are recorded of whole families who have exhibited this curious anomaly.

"THE USE OF THE AMBULANCE IN CIVIL PRACTICE."

IN a re-issue of a pamphlet bearing the above title Mr. Reginald Harrison quotes some painful instances of the hardships and dangers resulting from the conveyance of patients to hospitals by unsuitable methods. Fractures of the lower limbs, in particular, may be greatly aggravated in this way, either by the wounding of blood-vessels by the ends of the bone or by the conversion of a simple fracture into a compound one. Risks of another kind are incurred when a patient suffering from cardiac dyspnœa is taken to hospital in the upright position in an ordinary cab. In 1831 Liverpool possessed no ambulance resource of any kind except a two-wheeled conveyance resembling a costermonger's barrow used by the police. Mr. Harrison recollects being summoned to see two gentlemen who had had their legs fractured on ocean steamers arriving at that port, and he says that the crowds attracted by the spectacle of their removal to a hotel resembled a Royal progress, whilst a ship's captain suffering from a painful complaint when taken through the streets on the above-mentioned two wheeled conveyance was supposed by the mob to be intoxicated and jeered at accordingly. In contradistinction to these primitive and unsatisfactory methods Mr. Harrison commends the system in operation in some cities of the United States, where proper vehicles are kept at certain hospitals ready for instant despatch to the scene of an accident or emergency. Mr. Harrison gives a description of the ambulance vehicle belonging to the Massachusetts General Hospital at Boston and there is also an illustration of the removeable stretcher which forms a part of the vehicle. The pamphlet is published by Messrs. John Bale, Son, and Danielsson.

---

[1] THE LANCET, Nov. 27th, 1875, p. 767, with a sketch

THE SERUM TREATMENT OF LEPROSY.

IN his annual report on leprosy in New South Wales for the year 1898 Dr. J. Ashburton Thompson mentions that on Jan. 1st 13 persons remained under detention at the lazaret and that during the year nine persons were reported to the Board of Health under the Leprosy Act, 1890, as being suspected lepers. Four of them were eventually admitted to the lazaret under warrants issued by the Board. One, a Chinese, was allowed to return to China and another Chinese died in a Sydney hospital before his removal could be effected. The remainder were found to be suffering from some disease other than leprosy. Three patients died during the year, so that 14 remained in the lazaret on Dec. 31st, 1898. Four appendices are attached to the report. One of them describes the results obtained at the New South Wales lazaret with the serum treatment of leprosy, devised and strongly recommended by Dr. Don Juan de Dios Carrasquilla of Bogotá, Costa Rica, South America. Dr. Carrasquilla's method was to bleed lepers, to separate the serum, to inject it subcutaneously into horses, mules, or asses; to bleed these animals after they had received a sufficient number of injections; to separate the serum of their blood; and to inject this subcutaneously into persons suffering from leprosy. He stated that this treatment had been extraordinarily successful in about 100 cases of leprosy, and as there were rumours of success obtained by the method in other parts of the world, Dr. Frank Tidswell experimented with it at the New South Wales lazaret from August, 1897, till June, 1898. Four patients readily permitted venesection to be performed upon them. They were all suffering from tuberous leprosy in an active—i.e., a progressing—form. The venesections were performed in the usual way on the median basilic or median cephalic veins of the arm, the skin being previously washed and carbolised. The blood was received directly into a sterilised glass measuring cylinder, 250 cubic centimetres being removed at each operation. The cylinder, plugged with cotton-wool, was afterwards placed in a vessel packed round with ice and put away in a dark cupboard. In from 24 to 48 hours the serum was removed by means of a sterilised pipette into a sterilised flask, care being taken to avoid admixture with hæmoglobin. The leprous serum was injected into a horse, always within a few hours after its collection, so that there was no occasion to use camphor or other preservative. The injections were given subcutaneously into the chest or behind the shoulder, after previously shaving, washing, and carbolising the skin From Sept. 4th, 1897, to August 6th, 1898, the horse received 17 injections, the dose commencing at 30 and rising to 150 cubic centimetres. It was bled four times—namely, on Oct 3rd and Nov. 20th, 1897, and March 15th and June 3rd, 1898. For this purpose a sterilised trocar and cannula were passed into the jugular vein, the skin having been previously shaved, washed with soap and water, then with carbolic acid lotion, and finally with clean, recently boiled, water. On withdrawing the trocar the issuing blood was led through the cannula by attached indiarubber tubing into a sterilised glass jar plugged with cotton-wool. About 1500 cubic centimetres of blood were removed at each operation. When this amount had been obtained a clamp was tightly screwed on the rubber tubing near the jar and the rest of the tubing attached to the cannula was cut away. The jar of blood was then placed in a vessel, packed round with ice, and put away in a dark place In from 24 to 48 hours the serum was removed into a sterilised flask by means of a sterilised glass syphon. It was distributed into tubes containing each about 10 cubic centimetres by the following method. Pieces of glass tubing one centimetre in diameter and rather more than 10 centimetres long were sealed at one end and the other end was drawn out to a capillary point. The points were then passed through pinholes in thick indiarubber tubing connected with a Bunsen aspirating pump, and when a partial vacuum had been obtained the capillary part of each tube was sealed by a small flame. The tubes were then sterilised in the hot-air oven, and were filled by plunging the capillary part under the serum and breaking off its point with a pair of sinus forceps. The serum immediately almost filled the tube and the capillary part was then sealed. The serum was injected into the lepers under the skin of the flank in the usual way with an "antitoxin" syringe. Two patients underwent the treatment from Oct. 8th, 1897, to June 7th, 1898. One of them received 32 injections of five cubic centimetres each, two of 10, and one each of one and two cubic centimetres. The other patient received 32 injections of five cubic centimetres each, and one each of 10, two, and one cubic centimetres. The results obtained are summarised as follows in the closing *sentences of the paper.* "It will probably be conceded that Carrasquilla's method has been patiently and perseveringly tested by us Patients and physicians were equally anxious to give it every chance of success. Nevertheless, we have not found it produce the least improvement, but, on the contrary, the disease continued to progress in both patients. We are therefore obliged to regard Carrasquilla's method as inefficacious."

"NOT THE DISEASE ONLY, BUT ALSO THE MAN."

THE Shattuck Lecture for 1899 recently delivered by Dr. James Putnam before the Massachusetts Medical Society has just appeared as a reprint in pamphlet form. Dr. Putnam does much more in this contribution than merely to reiterate the truth embodied in the subject which forms the title of his lecture. He tells us how the "man" is to be treated, especially in those very numerous cases in which the disease presents a "psychical" as well as a bodily aspect. He points out clearly what is of value medically in hypnotism and its congeners—viz., the strong underlying element of suggestion. The mind or brain of man may be influenced, not only as an organ of thought, but as an organ of bodily nutrition and as the seat of forces which do not always recognise the personal consciousness as their ruler. Dr. Putnam would rate a sound knowledge of psychology in the physician *above a knowledge of botany* and zoology, and would make it the ground-work for the preparation necessary for medical study and practice. "The physicians who have previously been good students of psychology have in my experience proved themselves to be men of unusually broad sympathies and high ideals," says Dr. Putnam, "and keen to see causes of disease to which the pure pathologist is often blind No argument is needed to show what transforming power the mind may exert The energies set free by the magic agencies of hope, courage, desperation, fanaticism, or by the enthusiasm for a great cause, may reveal the possession of a force undreamt of, or so husband the resources of the body as to *keep the flame* of life burning for a time when the oil seems exhausted." The physician is by his profession an educator not only of children but of adults also, and above all of that multitude of persons whose lives are disordered or damaged by the so-called trivial neuroses which nevertheless cause an infinite amount of trouble and suffering in the world.

It is as meaningless as it is discouraging to tell a suffering person that his "pains are imaginary"—psychology recognises no such thing as imaginary pain The physician, says Dr Putnam, should give persistent encouragement, accompanied by such explanations as will enable the patient to understand and convince himself that the physician's cheery convictions will be realised Coaxing and training—a regulated discipline in conduct, in diet, and daily life—may all be employed as valuable adjuvants to dispel, for example, from the mind of the hypochondriac the fallacy and idleness of his notions In cases where such suggestion and advice are inadequate, hypnosis in its various degrees may be properly employed Rest and recreation, physical exercise, and literature should exert their powerful influence to get the sufferer out of his morbid psychological habits—out of his wretched self Dr Putnam preaches no new doctrines, but he has skilfully brought together useful facts and views having a distinct medico psychological value The physical and psychical aspects of man for purposes of therapeutics are not two but one, and of this fundamental fact the physician seeking ever to relieve cannot be too often reminded

EPILEPTIC ATTACKS WITH CRUDE SENSATIONS OF SMELL AND AN INTELLECTUAL AURA

IN the current number of *Brain* (Winter 1899-1900) Dr J Hughlings Jackson and Dr Purves Stewart record the following interesting case A B, a member of the medical profession aged 51 years, married, had enjoyed excellent health until three and a half years ago He then had a severe attack of septicæmia from which he recovered He remained well till October 1898 when he had septic cellulitis of his right hand and suffered from high fever (105° F) and occasional delirium, since which his general health had never been good He never had any head injury or otorrhœa at any time "Ever since his second attack of septicæmia the patient had been subject to occasional attacks of excitement without sufficient apparent cause He used to come home from his rounds in a state of excitement His general manner became different, his memory also became impaired and on one occasion he called to inquire for a patient who had long been dead' Two months before he came under observation he suffered from attacks of nausea and giddiness and experienced strong sensations (hallucinations) of smell, "like camphor or ether" The smell was succeeded by an intellectual aura, a condition in which he "felt as if he was saying, doing, and looking at things which he had experienced before and people and things seemed to be far away." His face expressed horror at such times, but there were no twitchings and he apparently did not lose consciousness He never had diplopia His sense of sight, of smell, and of taste seemed normal on both sides, but the left ear was slightly deaf The pupils reacted normally and there was slight optic neuritis in the right eye Cutaneous sensation muscular sense, and the knee jerks were normal He rapidly grew feeble and complained of headache in the right temporal region, his respiration grew faint at times and he finally passed into a state of coma The temperature rose to over 100° F and occasional clonic spasms of the left arm were observed on the night before his death A few days before death a slight left sided hemiplegia appeared, most marked in the face The case is clinically a very important one, especially as exhibiting the association of a crude olfactory aura with the dreamy state and with the emotion of fear in slight epileptic seizures Dr Hughlings Jackson has suggested for such cases the name of the uncinate group of fits[1] The case had been seen in consultation with Sir William Gowers and tumour of the temporo-sphenoidal lobe was diagnosed, but it was not regarded as a suitable case for operation

ROYAL ARMY MEDICAL CORPS FUND

AT the meeting of the Executive Committee of this Fund on Monday last subscriptions to the amount of £285 5*s* were announced in sums varying from 5*s* to £20 Gifts in kind had been received, purchases had been made, and 1200 parcels had been forwarded through Mrs Charlton to the front Several ladies have joined the committee since the last list was published, including Adeline Duchess of Bedford, the Marchioness of Hertford, the Countess of Essex, Viscountess Valentia, Lady Boston, and Lady Brownlow A great deal of interest is evidently being taken in the Fund by the public The honorary treasurer (Mrs Charters Symonds, 58, Portland-place) has also received several half-a crown subscriptions from medical men

THE MARINE HOSPITAL SERVICE OF THE UNITED STATES.

THE Surgeon General of the Marine Hospital Service of the United States in his report for the fiscal year ending June 30th, 1899 states that the past year has been the most active in its history The service owns and manages 22 marine hospitals and there are besides 107 stations where patients receive hospital or dispensary treatment During the fiscal year 1899 the total number of patients was 55 489, of which number 12 610 were treated in hospital At Fort Stanton, New Mexico the climate of which is in a high degree favourable to the treatment of tuberculosis, the department has had transfered to its use an abandoned military reservation with the object of its development as a sanatorium This measure will tend to relieve the marine hospitals of these contagious cases, as well as to aid in the great movement now being urged throughout America and other countries in suppressing a communicable disease The Marine Hospital Service also owns and manages 13 large and complete quarantine stations There were 3838 vessels inspected at these stations during the fiscal year In January, 1899, an order was signed by the President and the Secretary of War transferring all the maritime quarantine of Cuba and Porto Rico to the Marine Hospital Service In March another executive order was issued declaring that the expenses of this service should be paid from the revenues of the islands A thorough organisation was effected as soon as possible, there being at the present time some 30 officers of the service in Cuba and seven in Porto Rico On account of the increasing prevalence of plague in Asia and certain portions of Europe and Africa officers of the Marine Hospital Service have been detailed for duty at Honolulu, Yokohama, Hong-Kong, and Naples Perhaps the most interesting portion of the report is that which refers to the cause of yellow fever A commission of medical officers of the Marine Hospital Service were detailed by the President to make an investigation into the cause of this disease In the first place they verify the findings of Sanarelli in his discovery of the bacillus icteroides Further than this they demonstrate that the disease is received into the human system through the respiratory tract and indicate the probability of a serum similar in its use to that now employed in the treatment of diphtheria proving protective The report also draws attention to the success attending the efforts of the Government in Cuba in diminishing the prevalence of yellow fever by sanitation It is known that there are many seaports in the Western Hemisphere where yellow fever is endemic on account of bad

An inquiry is now being

---

[1] THE LANCET Jan. 14th 1899, p 79

of the Western Hemisphere, where yellow fever constantly prevails, with a view of definitely determining the reason therefore and proving, if possible, that it is due to want of proper drainage, sewerage, and cleanliness of the harbour. The report suggests that in the interests of commerce, as well as of life and health, the time may come when an international agreement may be effected between the republics of the Western Hemisphere by which the insanitary conditions which perpetuate this pest in certain ports will be considered a just cause of complaint by the other republics, when quarantine or other restrictions would be imposed by mutual agreement upon the Government possessing the offending port to cause it to adopt the necessary measures for the abatement of the evil.

THE STREETS OF LONDON IN THE MIDDLE AGES.

WE found it necessary on a recent occasion to complain of the way in which some of the London vestries neglect to carry out their statutory duties with regard to clearing the streets after a fall of snow. An alteration in the present method of street cleaning is much to be desired, and it would certainly be advantageous if water were more frequently and copiously used for flushing purposes. But although there is still much room for improvement a distinct advance has been made since the middle ages. The records of the city of London show clearly enough in what a filthy state the streets were formerly kept. The earliest regulations which were made with regard to the streets had reference to the preservation of order, and all those who wandered out after curfew were liable to summary arrest. Regulations for carrying out this edict were made in the reign of Edward I. and in the year 1297 a regulation was made with regard to cleaning the streets. It was enacted that everyone should keep clean the front of his own tenement, "that so the streets should be delivered from all encumbrances." A week's grace only was given before the regulation came into force, and after this interval the owner of any house was liable to be fined half a mark. At the same time it was ordered that all pigstyes should be speedily removed and that any swine found in the streets should be forfeited. In the reign of Edward II. (1309) a proclamation was made on the Sunday next before the feast of St. George the Martyr (April 23rd) that seeing people in the town caused the ordure that had been collected in their houses to be carried and placed in the streets and lanes instead of being taken to the Thames or elsewhere out of the town, and that the streets and lanes were more encumbered than they used to be, the Corporation forbade any person to permit the ordure, after it had been collected in his house, to be carried into the King's highway. Anyone breaking this regulation was liable to be amerced on the first conviction to the extent of 40*d.* and afterwards half a mark for each conviction, and he was, moreover, compelled to remove the dirt at his own expense. Another regulation made the owner of a house responsible for the state of the street, whether the nuisance was caused by himself or not. A penalty was incurred by any citizen before whose house dirt should be found, if after it had been placed there he did not immediately give information by whom it had been brought there. It seems to have occurred to those who framed the regulation that this enactment might be open to abuse, and they therefore in the same proclamation provided against such a contingency. It was enacted that if any person should have any dung carried or removed to the front of the house of any other citizen, he should be compelled to have it carried immediately from thence to *within* his own house, there to be kept a day and a night on pain of a fine of a like amount to that provided for the cases previously referred to. It appears from this that the rascality of removing dirt to the front of the house of a neighbour was to be punished in a way which is not in accord with modern sanitary teaching. This punishment, however, is not unlike others which were inflicted about the same date in the city of London; for example, a man who sold inferior and sour wine was publicly made to drink a large quantity of it himself. The refuse in the streets caused great trouble in the middle ages and the method adopted of simply putting it into the Thames naturally caused a very considerable nuisance on the river banks, so that in the reign of Edward III. (1357) the king made a complaint on the matter to the Mayor and Sheriffs of the city. His Majesty remarked that the accumulation of filth in divers places not only in the city but also on the banks of the Thames caused fumes and other abominable stenches from the corruption, by which, if tolerated, great peril would ensue as well to the persons dwelling within the city as to the nobles and others passing along the river. Wishing to take precautions against such dangers and to preserve the honour and decency of the city, the King commanded that the banks of the river and the streets of the city should be cleansed without delay and kept clean in the future, and if any persons thereafter were found breaking this regulation they were to be chastised and punished so that fear might prevent others from committing a like offence, "and this," the royal order concludes, "as you would preserve yourself safe and would avoid our heavy indignation you are in no wise to omit." This writ was proclaimed on the Thursday after the Feast of the Decollation of St. John (August 29th). In the reign of Richard II. the Common Council, by the advice of the Mayor, Aldermen, and Commonalty ordained that the ordinance in force against the accumulation of filth should be strictly enforced, that no one should throw rubbish into the kennels of the city in the time of rain, and that every officer should have power to take the carts which brought in gravel and sand and load them at their departure with the filth gathered from the kennels, so that it should be carried out of the city. This process of commandeering was, however, to be applied only to the vehicles which carted sand, gravel, and loam into the city. It is evident from these few quotations from the city records that at any rate some advance has been made towards a better regulation of the streets, although not a little yet remains to be done.

THE INFLUENCE OF ALCOHOL ON THE RESPIRATION IN MAN.

THE seventy-sixth volume of Pflugers "Archiv fur die gesammte Physiologie" contains an article by Dr. H. Wendelstadt of Bonn in which he gives the results of his experiments on the action of alcohol upon the respiration in several persons with a view of determining its pharmacological value. A small gasometer was closely applied to the mouth whilst the subject was in a recumbent posture and each observation lasted 10 minutes, the quantity of air breathed being read off every 10 seconds. In some of the later experiments the number of respirations was also counted. The temperature of the room was kept, as nearly as possible at 65° F. and the experiments were conducted partly in the morning, when no fatigue had been undergone, and partly on subjects who were more or less exhausted after muscular or mental effort. Wine or pure alcohol mixed with sweetened lemonade was administered in moderate doses. Thus in one case 100 cubic centimetres of sherry containing 17 cubic centimetres of alcohol, in another case 15 cubic centimetres of alcohol in lemonade, in another a pint bottle of champagne, were given, usually on a fasting stomach. In most cases much drowsiness or even heavy sleep was induced. The general results obtained in men who were not fatigued were that in one experiment there was no alteration in the volume of air respired, in nine experiments there was a diminution, and in 54 cases there was an increase after the use of alcohol, but with much individual variation. In 29 cases in which pure alcohol was ingested seven showed diminution of the respiratory activity, but when the alcohol was taken in the form of wine only two showed such diminution while the amount of increase in every case where it occurred was greater. The difference, Dr. Wendelstadt thinks, is attributable to the presence of ethereal oils in the wine giving it its bouquet. It must be borne in mind that, although it has been found that the administration of 100 cubic centimetres of pure water does not augment the volume of respired air in a given time, yet the same quantity of water with sugar and lime-juice causes in some instances at least a slight increase. In those who are exhausted by fatigue the effects of alcohol in causing an increase in the volume of air breathed are much more marked. Now, in febrile and debilitated states of the body the condition of the nervous system resembles that of one who is exhausted by fatigue, and hence Dr. Wendelstadt's experiments corroborate the conclusion arrived at by most clinical observers that in such conditions alcohol, especially in the form of wine, having much aroma, is the best stimulant that can be given.

THE APPOINTMENT OF A COUNTY MEDICAL OFFICER FOR MONMOUTHSHIRE.

THE Local Government Act of 1888, which established county councils throughout England and Wales, entrusted to these authorities the execution of certain laws relating to public health and in order that these duties might be more satisfactorily carried out provision was made for the appointment of a county medical officer of health. Although eleven years have elapsed since the Act came into force only one of the Welsh councils has availed itself of this power, notwithstanding the fact that the greatest benefit to the counties has admittedly resulted in every instance where in England an appointment has been made. If the question of cost is put aside—and this can be a factor only in the smallest counties—it is a little difficult to understand the position of those who oppose proposals to appoint such an official. It is evident from the discussion which took place at the last quarterly meeting of the Monmouthshire County Council at Newport that a majority of the members of this body are ignorant not only of the powers which they as a council possess, but of the duties which devolve upon them. In the spring of last year the sanitary committee were instructed by the council to report as to the desirability of appointing a county medical officer of health and to advise as to the details of the appointment. The committee can hardly be accused of coming to a hasty decision, for after deliberating for nearly a twelvemonth they recommended that a medical officer should be appointed at a salary of £500 per annum with an additional £100 for travelling expenses. This recommendation was outvoted solely on the plea that a medical officer of health had "no power." If the Monmouthshire County Council, having a sense of their great responsibilities, will confer with the members of other county councils—say those of Staffordshire or of Cheshire—their views will probably undergo material change. They are doubtless already aware that every district medical officer of health is required to send to the county council copies of all his reports, but they evidently do not know that something more than the bare reception and pigeonholing of these documents is required of the county council. One section of the Local Government Act imposes upon the county council the duty of making a representation to the Local Government Board when it appears to the council from any of these reports that the Public Health Act, 1875, has not been properly put in force within the district to which the report refers or when it appears that any other matter affecting the public health of the district requires remedy. How is it possible for the Monmouthshire County Council to properly carry out this duty without the assistance of a medical officer of health? Other statutory obligations imposed upon county councils, which can only be performed in the most perfunctory manner where the services of such an official are not available, are included in the Rivers Pollution Prevention Act and the Isolation Hospitals Act. The Housing of the Working Classes Act, 1890, empowers a county council to close houses that are unfit for habitation, and the Local Government Act of 1894 enables a county council to enforce the provision of sewers and of a sufficient water-supply in rural districts; but no adequate action can be taken in these matters by county councils who have not yet appointed a medical officer of health.

THE INTERNATIONAL MEDICAL CONGRESS, PARIS, 1900.

THE Paris Executive of the International Medical Congress give notice that as there has been some misunderstanding about the sectional arrangements every member may join as many sections as he pleases for a single subscription, but that the expense will prevent every member receiving a copy of the whole 24 volumes of the Proceedings of the Congress. Each member of the Congress will receive therefore in due course: (1) a general *résumé* of the work of the Congress; (2) a volume of the Acta of the Congress; and (3) a volume containing the works of the section to which he chooses to affiliate himself. If a member has joined several sections he will receive the Proceedings of the section which he has placed first on his form of application for membership. Members of the Congress who wish to receive the whole set of Proceedings should communicate with M. Masson, the editor, 120, Boulevard St. Germain, Paris.

THE GENERAL HOSPITAL, TUNBRIDGE WELLS.

THE annual meeting of governors of and subscribers to the General Hospital, Tunbridge Wells, was held on Jan. 7th, the Marquis of Camden being in the chair. The treasurer pointed out that although the subscriptions for the past year had been above the average, yet, owing to there being a debt of £538 due from 1898, the bankers' account had been considerably overdrawn and they had been obliged to sell out some stock. A scheme for the extension of the hospital had been approved, and they were only waiting for funds to commence the work. Before the report was put to the meeting Dr. John E. Ranking, the senior physician to the hospital, said that, speaking simply as a governor and not as a member of the staff, he wished to bring forward a matter of great importance. Leave having been given, Dr. Ranking referred to some letters which had appeared, although unsigned, in the local press reflecting upon the management of the hospital. The letters had expressed great dissatisfaction with the treatment of the out-patients, who were kept waiting a very long time. Dr. Ranking also read letters addressed to him personally expressing the same views. The complaints, he said, might be ranged under three headings: first, those bringing general complaints; secondly, those alleging extravagance in the administration; and thirdly, those dealing with the delay in the out-patient service. He would only deal with the last of these and the reason of the delay, he said, was very simple—they were attempting to do modern work with antiquated machinery. The machinery at present existing was the same for all practical purposes as when he joined the staff 20 years ago and even then it was barely sufficient. If they wished for better work they must provide more perfect machinery. We must confess that the desire to carry on work on a modern scale with antiquated machinery is a policy not confined to hospitals. But it is always a wasteful and extravagant policy and one bad from every point of view. Of whatever kind of work the output consists a policy of starvation never pays. In a hospital this policy is peculiarly hurtful and we gather from remarks made at the meeting that the staff are supposed to perform impossibilities. Mr. Elers, the treasurer, is reported as saying that in this case it was a question whether these gentlemen should not be asked to resign, but we are glad to say that this remark did not meet with the approval of Mr. Elers's hearers. Eventually a motion put forward by Dr. Ranking as follows was carried :—

> That a special committee, consisting of the president, the treasurer, the mayor, the two senior medical officers, and four other governors who are not members of the committees, together with some recognised expert in hospital administration, be appointed to consider the whole question of the future administration of the General Hospital, and that after the completion of all necessary business this annual meeting be adjourned until such committee do report.

We are glad to see that the meeting arrived at these conclusions. If charges are made against a hospital it is of vital importance that they should be inquired into. If the abuses referred to do exist they should be rectified as soon as possible and if they do not then the sooner the allegations which have been made are refuted the better for everyone concerned.

TYPHOID PLEURISY.

AT the meeting of the Société Médicale des Hôpitaux of Paris on Jan. 19th MM. *Souques*, *Lesné*, and Ravaut reported from the clinic of Dr. Chauffard two cases of typhoid pleurisy which occurred during the last epidemic of typhoid fever in Paris. Typhoid pleurisy—due to Eberth's bacillus—is rare. Labiche recently could only collect 10 cases (Thèse de Paris, 1899) In the first case reported to the society a youth, aged 18 years, had on the fourth day of an ordinary attack of typhoid fever violent pain in the lower part of the chest on the left side There were disseminated sibilant râles and some sub crepitant râles at both bases. The pain continued and on the twelfth day there were at the left base slight dulness and pleural friction. On the following day puncture gave exit to 10 cubic centimetres of a hæmorrhagic liquid containing the typhoid bacillus in abundance. On the twentieth day puncture gave exit to two cubic centimetres of a purulent liquid still containing in pure culture the typhoid bacillus. The liquid was replaced by two cubic centimetres of camphorated naphthol. On the twenty-third and again on the twenty-ninth day some hæmorrhagic fluid containing the typhoid bacillus was aspirated. Recovery ensued. In the second case a man, aged 31 years, entered hospital on the seventh day of an attack of typhoid fever. Some days previously he felt a sharp pain in the back especially on the right side. There were tubular breathing and large moist râles at the right apex. On the fifteenth day the patient complained of dyspnœa and the temperature which was falling rose to 105·4° F. The right lung became infiltrated from apex to base. The sputum was muco-purulent and contained pneumococci, staphylococci, and bacilli resembling Eberth's (cultures were not made in consequence of the presence of numerous saprophytes). Signs of pleuritic effusion then became evident. On puncture hæmorrhagic fluid containing the typhoid bacillus in pure culture was obtained. Recovery ensued. Pleurisy complicating typhoid fever is not necessarily due to the typhoid bacillus, but may result from an additional infection with tubercle bacilli or streptococci. Also the typhoid bacillus may co-exist in the pleura with other microbes, and then it is difficult to ascertain its individual action In the above two cases the pleurisy supervened at the beginning of the fever; in those previously recorded it has occurred usually at the decline. As a rule a pulmonary lesion precedes the pleurisy, which possibly is also due to the typhoid bacillus. Typhoid pleurisy is more often purulent than hæmorrhagic: it may also be sero fibrinous. A fact which is difficult of explanation is that the effusion sometimes gives the agglutinative reaction and sometimes does not.

A BACTERIOLOGIST FOR THE IRISH LOCAL GOVERNMENT BOARD.

THE newly created office of bacteriologist to the Irish Local Government Board has been filled by the appointment of Professor E. J McWeeney of Dublin. *Professor McWeeney* has for several years occupied the chair of Bacteriology and Pathology at the medical school of the Catholic University, Dublin, and is well known as an earnest worker on the scientific side of medicine This appointment is of importance as marking a new departure in the history of public health administration in Ireland. To English hygienists it has long been a matter of surprise that the Irish sanitary authorities should have been so slow—some might be inclined to use the adjective "remiss"—in availing themselves of the powerful weapons of precision which bacteriological science places in our hands for the elucidation and prevention of infectious disease. In one of the series of articles on the health of Dublin which have recently been appearing in our columns our Special Commissioner took occasion to draw attention to this singular *lacuna* in the Public Health Service of the sister isle. It is satisfactory that steps have now been taken by the authorities to press bacteriology into the service of sanitation, and it is to be hoped that the chief municipalities and county councils throughout Ireland will by appointing bacteriologists speedily follow the example which has been set them by the Local Government Board.

MEDICAL REPORTS OF THE CHINESE MARITIME CUSTOMS.

THE printed and published reports of the Chinese Imperial Maritime Customs for the half year ended March 31st, 1899, are by seven contributors, five of whom write in English—namely, Mr. J. F. Molyneux of Chefoo, Dr. J. H. McCartney of Chungking, Dr H. J. Hickin of Ningpo, Dr B. S. Ringer of Canton, and Dr. R. J. J. Macdonald of Wuchow. The remaining two memoirs are in French; one is by Dr. A. Thoulon, of the French Navy, who sends from Longtcheon (or Lungchow) notes on bubonic plague at Ping-s'hiang (Kwangsi); the other is a sanitary report on Mongtze (or Mengtsz) by Dr. E. Reygondaud of that place. According to all these writers there was in the period under review no prevalence of epidemic disease except plague and influenza. Dr. McCartney makes a reference to the wearing of cholera belts, which he believes very often do more harm than good He has treated several patients for chronic bowel trouble who made a rapid recovery when they discarded the belt. Part of the danger, he says, lies in the belt working up under the arms during sleep and allowing the abdomen to become chilled. With respect to maternity cases he remarks that in shoulder presentations the Chinese midwives are unable to do anything, and they invariably pull off an arm in their frantic efforts to deliver the child. Dr. Macdonald mentions that lepers in Wuchow are allowed to dwell among their own people long after the distinct development of the skin and nerve affection, but nevertheless the disease is not so prevalent as might have been expected. When spontaneous amputation of digits or leonine pression of countenance occur the sufferer is usually banished from his home These reports are published by the Inspectorate General of Customs Shanghai, and may be obtained in London from Messrs P S King and Son

THE FESTIVAL DINNER OF KING S COLLEGE, LONDON

In another column will be found a report of the proceedings at this dinner which may be summarised by saying that Mr Balfour delivered an admirable address on the claims of science upon the community No scientific man, and we may say no really enlightened citizen, would desire to see a word altered in Mr Balfour s excellent speech We hope that it will be widely read and that it will lead in the immediate future to the accomplishment of its direct object

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY

THE annual dinner of this society was held at the Café Monico on Wednesday evening last The President Dr J B Ball, filled the chair The attendance was large, the dinner was good, and the music and speeches were appropriate The speakers were the President, Mr Gunton Alderton, Mr Howard Marsh Dr Frederick Roberts Mr C B Keetley, Mr Butlin Mr Herbert Menzies Dr Lamb, and Mr H Percy Dunn The society seems to be the largest and most flourishing of the local societies of London, having a membership of over 500, which is still increasing The society is based on democratic principles and does not have figure heads a fact which no doubt increases both its popularity and utility While not neglecting scientific subjects it cultivates good fellowship and takes a proper interest in the prosperity of the profession

ALCOHOL AS AN ANTIDOTE IN CARBOLIC ACID POISONING

IN a recent number of *Merck s Archives* (December, 1899) an editorial article is devoted to the above subject The writer of the article observes that alcohol, as was first suggested by Phelps and Powell, is one of the best antidotes for carbolic acid poisoning Phelps declared that he had found in alcohol a safe and sure preventive against the escharotic action of concentrated carbolic acid which was the mischief most to be feared in cases of poisoning by the strong acid From a careful survey of recorded cases of carbolic acid poisoning, in which over 60 grains of the poison had been taken, it appears that where no alcohol was administered the termination was in every case fatal On the other hand in all instances where alcohol was given the patient survived although it is stated in more than one instance that it was given as a stimulant to prevent collapse rather than with the knowledge that it acted as a specific antidote The article also points out that it is often difficult and sometimes impossible to get emetics to act successfully in such cases of poisoning The method of treatment which is recommended is as follows The patient is promptly made to drink a few ounces of whisky, brandy or other spirit which thus acts as an antidote to the intense local action of the carbolic acid in the stomach Immediately after this a soft indiarubber tube is passed through the œsophagus and into the stomach A funnel is attached to its upper end and about a pint of water (more or less, according to circumstances) is poured into the stomach The upper end of the tube is now depressed and the fluid is syphoned out This process of washing out the stomach is repeated two or three times and in this way every particle of the poison can be washed out of the stomach A little sodium sulphate is next administered, a dose of about one drachm dissolved in a wine glassful of water being sufficient It may be noted that if the water used for washing out the stomach contains any notable proportion of a soluble alkaline sulphate its efficiency is increased Moreover the small amount of it which may pass from the stomach into the duodenum and small intestine will be of use in aiding the elimination of part of the poison which has entered or become absorbed into the coats of the small intestine The addition of a small quantity of sodium sulphate to the water used in washing out the stomach would thus be of distinct value, and the method of treatment advocated above promises to give more favourable results than are usually obtained in grave cases of poisoning by carbolic acid

THE PRINCE OF WALES S HOSPITAL FUND FOR LONDON

AT the annual meeting of the General Council of the Prince of Wales s Hospital Fund held on Feb 13th at Marlborough House H R H the Prince of Wales in the chair the draft report for the past year was read and adopted The receipts for 1899 were £48 536 15*s* 4*d*, being an increase of about £9000 over those of 1898 The total sum distributed for the year amounted to £42,000, £26,250 being annual grants and the balance donations We congratulate the Prince of Wales and his coadjutors on their work to which we shall make longer reference

THE CARE AND MAINTENANCE OF NON-PAUPER LUNATICS AND THE LONDON COUNTY COUNCIL

IT is among the merits of the London County Council that it has shown much consideration for the insane and for their responsible relatives The case of such relatives in moderate circumstances is often extremely painful The shock of mental illness overtaking a member of the family is sadly complicated with the financial question of his maintenance in an asylum without subjecting him to the ordeal of admission as a pauper lunatic The London County Council has recently announced to medical practitioners that it has provided accommodation for about 60 female patients having a legal settlement in the county of London at the Manor House Horton Epsom, at a weekly charge as at present fixed of 15*s* this being exclusive of clothing and special luxuries Full particulars can be obtained from Mr R W Partridge clerk of the Asylums Committee This is not the first service of the sort rendered to the insane At the London County Asylum Claybury, Woodford, Essex, provision is made for private patients who can claim a settlement in the county of London at a charge of 30*s* a week, and for others at a charge of £2 The London County Council, too has not been unmindful of the higher duties of a lunacy authority—that of providing for research and investigation into the pathology of insanity The first report of the work of Dr F W Mott, F R S, with a preface by Dr W F Collins, shows how thoroughly this work—suggested at an early stage of the history of the Council by Mr Brudenell Carter—is being carried out

AT the last meeting of the council of the St Andrews Graduates Association, which was held at 11, Chandos street Cavendish square the following resolution was unanimously adopted ' That action be taken with a view of restoring to the University the right which it so long possessed of granting the degree of Doctor of Medicine to registered practitioners of 15 years' standing who are not under 40 years of age on their passing a full and satisfactory professional examination The Council in so doing are only seeking to place the University in the position which the University of Durham now holds and they desire to ask without prejudice to the other Scottish universities which may wish to exercise the like power of graduation."

THE chairman and committee of the Society for Training Teachers of the Deaf and for the Diffusion of the German (pure oral) System will hold a festival dinner in aid of its Training College and School at the Victoria Hall of the Hotel Cecil, on Wednesday next, Feb. 21st. The Marquis of Londonderry will take the chair. Communications should be made to the chairman, 33, Cavendish-square, W.

AT the meeting of the Epidemiological Society which is to be held to-night (Friday, Feb. 16th) Dr. E. W. Hope, medical officer of health of Liverpool, will read a paper, illustrated by lantern slides, on Insanitary Property and Workmen's Dwellings in Liverpool.

AT the polling for the election of a new Member of Parliament for the University of London the figures were as follows: Sir Michael Foster, 1271; Dr. Collins, 863; and Mr. Busk, 586.

Mr. W. H. Power, F.R.S., medical officer to the Local Government Board, has been appointed a member of the Royal Commission on Sewage Disposal.

THE new Enfield Isolation Hospital at Winchmore-hill was opened by Sir Walter Foster, M.D. Erlang., M.P., on Feb. 10th.

FOR the week ending Feb. 8th seven fresh cases of bubonic plague, five fatal, are reported from Mauritius.

THE MIDWIVES BILL.

[We refer our readers to the leading article on page 472, and beg that they will accede to the request therein contained.]

THE following is the text of the Bill which was introduced by Mr. Tatton Egerton in the House of Commons on Feb. 2nd and which has been set down to be read a second time on Feb. 28th. The new matter is printed in italics and where the alterations have been made at the suggestion of the Privy Council an asterisk precedes the passage. The words "certificate" and "licence" have been transposed throughout the 1899 Bill, so that the certificate now admits to the roll, while the licence is to be granted annually by the local supervising authority.

ARRANGEMENT OF CLAUSES.

Clause.
1. Short Title and *date of commencement of Act.*
2. *Certification.*
3. Provision for existing midwives.
4. Constitution and duties of the Central Midwives Board.
5. Fees and expenses.
6. *Power to County Councils to contribute.*
7. Midwives roll.
8. Appointment of Secretary. Supplemental provision as to certificate.
9. Local supervision of midwives.

Clause.
10. *Delegation of powers of County Council to District Councils.*
11. Midwives licence.
12. Penalty for obtaining *a certificate* or a licence by false representation, or acting without a certificate or a licence.
13. Penalty for wilful falsification of roll.
14. Prosecution of offences.
15. Appeal.
16. Act not to apply to medical practitioners.
17. Extent of Act.
18. Definitions.

A BILL

TO SECURE THE BETTER TRAINING OF MIDWIVES AND TO REGULATE THEIR PRACTICE.

BE it enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. This Act may for all purposes be cited as the Midwives Act, 1900. *It shall come into force on the first day of April, 1901.*

2. (1) From and after the first day of January one thousand nine hundred *and two* no woman shall be entitled to take or use the name or title of midwife (either alone or in combination with any other word or words), or any name, title, addition or description implying that she is certified under this Act, or is qualified to act as a midwife unless she be certified under this Act.

(2) Any woman who, after the first day of January one thousand nine hundred and two, not being certified under this Act, shall take or
use the name of midwife or any other such name, title,
description as aforesaid, or shall habitually and for gain att
in childbirth, shall be liable on summary conviction to
exceeding five pounds.

(3) No woman shall be certified under this Act until she h
with the rules and regulations to be laid down in pursu
terms of this Act.

(4) *No woman certified under this Act shall employ as her*
assistant an uncertified person.

(5) The certificate under this Act shall not confer upon
any right or title to be registered under the Medical Acts c
any name, title, or designation implying that she is by law
as a medical practitioner, or that she is qualified to grant
certificate, or *any certificate of death or of still-birth or to*
of abnormal labour, or of disease of or danger to the mother o

3. Any woman who, within two years from the date
coming into operation, claims to be certified under this A
so certified provided she holds a certificate in midwifery fro
College of Physicians of Ireland, or from the Obstetrical
London, or such other certificate as may be approved by
Midwives Board, or produces evidence satisfactory to the
at the passing of this Act she has been in bonâ fide practi
wife and that she bears a good character.

4. On the passing of this Act the President of the Gene
Council shall take steps to secure the formation of a Centra
Board, which shall consist of—

(1) Four registered medical practitioners, one to be app
the Royal College of Physicians of London, one b
College of Surgeons of England, one by the Society
caries, and one by the Incorporated Midwives Instit

(2) Two persons (one of whom shall be a woman) to be
for terms of three years by the Lord President of t
and

(3) *One person to be appointed for terms of three ye*
Association of County Councils.

After two years from the date of this Act coming int
the members appointed under Clause 4, Section 1, shall
shall be eligible for re-appointment annually. *Any vacanc*
by resignation or death shall be filled up in the case of
appointed under Clause 4, Sections (1) and (3), by the b
appointed him, and in the case of a member appointed unde
Section (2), by the Lord President of the Council.

The duties of the Board shall be as follows:—

I. To frame rules, *subject to the approval of*[2] the Gene
Council,

(a) regulating the issue of certificates and the condit
mission to the roll;

(b) regulating the course of training and the conduct
tions;

(c) regulating the admission to the roll of women alrea
tice as midwives at the passing of this Act;

(d) regulating, supervising, and restricting within du
practice of midwives;

(e) deciding the conditions under which midwives may be
from practice.

II. To appoint examiners;

III. To decide upon the places where, and the ti
examinations shall be held;

IV. To publish annually a roll of midwives who hav
certified under the Act;

V. To decide upon the removal from the roll of the
midwife for disobeying the rules and regulations f
time laid down under this Act by the Central Midw
or for other misconduct, and also to decide upon
tion to the roll of the name of any *midwife so remov*

VI. To issue certificates;

And generally to do any other act or duty which may b
for the due and proper carrying out of the provi
Act.

5. There shall be payable by every woman presenting
examination or certificate such fee as the Central Midw
may, with the approval of the General Medical Council, f
time determine, such fee not to exceed the sum of one guine
fees paid by existing midwives and by candidates for exami
be paid to the Central Midwives Board. The said Board
such fees to the payment of expenses connected with the e
and certificate and to the general expenses of the Boa
these fees not equal the expenditure of the Board the defic
be supplied from the respective local county funds, in p
the number of midwives licensed to practise in the said cou

6. * *(1) A county council shall be empowered to pay out of the c*
as general expenses incurred by them in the execution of
under the Local Government Act, 1888, any sum from t
required to make good a deficiency in the funds of the Centra
Board. (2) Such expenses as the Treasury may certify
necessarily incurred by the General Medical Council in the e
this Act shall be defrayed out of money provided by Parliam

7. There shall be a Midwives Roll containing:—

(1) The names of those midwives practising at the
passing of the Act who have been certified to pr
the Act;

(2) The names of those not already in practice as mid
passing of the Act, but who have been certified
under the Act.

The entry on the roll shall in every case indicate conditio
of which the certificate was granted.

8. The Central Midwives Board shall appoint a secretary
charged with the custody of the roll, **and every person*
shall be paid such salary as the Board shall think fit a
removable at the pleasure of the Board.

A copy of the Midwives Roll for the time being shall be
all courts that the women therein specified are certified
the provisions of the Act; and the absence of the name of
from such copy shall be evidence, until the contrary
appear, that such woman is not certified *according* to th

---

[1] For "elected."

[2] For "for approval by."

of this Act. Provided always, that in the case of any woman whose name does not appear in such copy a certificate under the hand of the secretary of the entry of the name of such woman on the roll shall be evidence that such woman is certified under the provisions of this Act.

9 Every county council * *or council of a county borough* throughout England and Wales shall, on the date of this Act coming into operation, *constitute the local supervising authority over midwives*[3] within the area of the said county or county borough It shall be the duty of the local supervising authority—

(1) *To issue licences*

(2) To exercise general supervision over all midwives practising within the prescribed area in accordance with the rules to be laid down under the provisions of this Act.

(3) To investigate charges of malpractice, negligence, or misconduct on the part of any midwife practising within the district, and, should a *primâ facie* case be established, to report the same to the Central Midwives Board.

(4) To suspend any midwife from practice, in accordance with the rules to be laid down by the Central Midwives Board **and approved of by the General Medical Council*, if such suspension appears necessary to prevent the spread of infection.

(5) To report at once to the said Board the name of any midwife practising in the district convicted of a misdemeanour or felony

(6) During the month of January of each year to supply the secretary of the Central Midwives Board with the names and addresses of all midwives practising in the district and to keep a current copy of the Midwives Roll, accessible at all reasonable times for public inspection

(7) To report at once to the Central Midwives Board the death of any midwife or any change in the name or address of any midwife in the district, so that the necessary alteration may be made in the roll.

10 **A county council may delegate, with or without any restrictions or conditions as they may think fit, any powers or duties conferred or imposed upon them by or in pursuance of this Act, to any district council within the area of the county*

11 *No woman shall* hold herself out as a practising midwife in any county or *county borough* without having previously obtained from the local supervising authority a licence enabling her to practise therein, which licence shall be granted on proof by the woman that her name is on the Midwives Roll The licence shall remain in force till the thirty first of December following and shall be revocable at any time by the local supervising authority in case the holder be proved to the satisfaction of the Central Midwives Board to have infringed any of the regulations framed under this Act The licence shall be issued on payment of a fee of one *shilling*,[4] it shall only be available in the county for which it is issued, and it shall be renewed annually on the *first day* of January

12 (*a*) Any woman who procures or attempts to procure a certificate or a licence by making or producing or causing to be made or produced, any false or fraudulent declaration, certificate or representation, either in writing or otherwise, and any person assisting her therein shall be deemed guilty of a misdemeanour, and shall on conviction thereof be liable to a fine not exceeding five pounds, or to be imprisoned, with or without hard labour, for any term not exceeding two months

(*b*) Any woman whether certified under this Act or not, who, after the first day of January one thousand nine hundred and two, shall hold herself out as a practising midwife or shall practise in any county or *county borough* without having previously obtained from the local supervising authority a licence enabling her to practise therein shall be deemed guilty of a misdemeanour, and shall, on conviction thereof, be liable to a fine not exceeding two pounds or *to* be imprisoned, with or without hard labour, for any term not exceeding one month.

(*c*) But a midwife shall not be guilty of a misdemeanour under this section by attending on an emergency a woman in childbirth in a county other than that for which she holds a licence provided she has within a reasonable time given notice of having so acted to the local supervising authority of the county

13 *Any person* wilfully making or causing to be made any falsification in any matter relating to the roll of midwives shall be deemed guilty of a misdemeanour and shall be liable to a fine not exceeding ten pounds, or to be imprisoned, with or without hard labour, for any term not exceeding three months

14. Any offences under this Act punishable on summary conviction may be prosecuted by the local supervising authority, and any fine under this Act recoverable on summary conviction may be recovered in manner provided by the Summary Jurisdiction Acts

The expenses of any prosecution shall be defrayed out of the funds of the county in which the prosecution takes place

15 (1) An appeal shall be allowed to the Privy Council should any disagreement arise between the General Medical Council and the Midwives Board respecting the carrying out of the provisions of the Act or any of them.

(2) Where any woman deems herself *aggrieved* by any order, conviction, judgment, or determination of or by any matter or thing done under this Act by any court of summary jurisdiction, such woman may appeal therefrom to the court of quarter sessions.

16 Nothing in this Act respecting midwives shall apply to legally qualified medical practitioners

17 This Act shall not extend to Scotland or Ireland.

* *The General Medical Council shall act by the English Branch Council, which for all purposes of this Act shall occupy the place of the General Medical Council*

18. In this Act—

The term "midwife" means a woman who undertakes for gain, *and in accordance with the provisions of this Act*, to attend women in childbirth

"Midwives roll" means a roll of midwives kept in pursuance of this Act.

"Central Midwives Board" means the Board constituted under this Act for the purpose of carrying out the provisions of this Act.

---

[3] This clause formerly provided for the appointment of "the medical officer of health or other registered medical practitioner or practitioners" as the local supervising authority within the county area.

[4] In the previous Bill the certificate was issued free

THE WAR IN SOUTH AFRICA

WE regret to say that from a military point of view there has been nothing of a favourable nature to chronicle during the past week The progress of the war only serves to bring out more strongly the great natural strength of the Boer positions and the extraordinary scope of the preparations which they had been making for so long beforehand. To take only one point in illustration. When one regards the enormous amount of labour entailed by the transport and placing of numerous heavy guns of position at so many elevated points in a mountainous country we are almost tempted to go back to the time of the Pharaohs and the building of the pyramids in Egypt for a similar expenditure of physical force The work must have been going on for some time, and if, as reported, 100 guns have been mounted between the Tugela and Ladysmith it is a marvellous performance and must have required a very large amount of native labour and a great number of horses and oxen for its accomplishment It certainly seems surprising that we should apparently have been so ignorant of all that was being done We are now reaping, at any rate, a severe punishment for our ignorance or negligence in the past

Apart from the vacillating and contradictory policy which has more or less characterised successive Governments in dealing with South Africa in the past and the miscalculations which have taken place in the present, the absence of any thoroughly reliable Ordnance or military map has been a cause of grave embarrassment It appears that towards the end of 1884 the officer commanding the Royal Engineers in Natal proposed that a survey should be made of the passes over the Drakensberg, but this, for political reasons, was not then considered desirable, lest, we suppose, it should give umbrage to the Transvaal Government Taken altogether, our patience, and forbearance, and desire to avoid all provocation have cost this nation a large loss of life and treasure, and have given rise to several military movements which have proved futile and need not have taken place. It is now sufficiently obvious to everyone that the war at its outset gave rise to situations and to political and other complications that were unexpected and unforeseen. The plan which Sir Redvers Buller was known to have drawn up when he reached Cape Town had consequently to be temporarily set aside It or a plan of a similar nature is now to be carried out The movements upon the frontier of the Orange Free State should draw off the Boer forces from the vicinity of the Tugela and Ladysmith and afford General Buller a much more favourable chance of relieving the garrison of the latter place The beginning, middle, and end of the requirements of a large army in the field may be said to be transport, of which ambulance and sick transport form an essential part. The transport arrangements have probably now been completed and the military role of Lord Roberts and Lord Kitchener has now to come The undertaking in South Africa is a formidable and anxious one, but a nation that emerged successfully out of the Crimean War and the Indian Mutiny may be expected to do the same on the present occasion. The resources of the empire are immense and the determination, enthusiasm and energy of its people are unabated

But to turn to matters of a medical nature It is astonishing how difficult it is to guard any system intended for the relief of the wounded of belligerent armies from abuse The modern medical system in war is, as we have repeatedly said, about the best that could be devised for the purpose; but the first collection and dressing of the wounded have, we learn given rise to some misunderstanding and recrimination on one side or the other. Some time ago General Cronje intimated that he would pay no further attention to the Red Cross when it appeared in the firing line The appearance of ambulances in the fire zone is open to the objection that they may be used, on the one hand, to afford protection to men firing near them, and, on the other, to enable ammunition to be carried, under cover of the Red Cross, to the fighting ranks Moreover, we have had allegations of the improper treatment of the Geneva flag, just as we have of the unscrupulous use of the white flag. It is probable that some of these allegations as regards firing on ambulances and hospitals have been altogether unfounded. The firing was either unavoidable or occurred in mistake under the excitement of the battle-field. Allowances must consequently be made and explanations may be forthcoming in regard to a number of such occurrences, but it is quite a different matter when unfounded and mischievous reports are circulated in reference to the conduct of the military medical service and its hospitals. There are to be found, we regret to say, on all such occasions as the present, people who are ready to indulge in an unworthy spirit of fault-finding and adverse criticism which is almost always ungenerous and commonly unjust, or is the result of superficial and insufficient investigation. It was so, it will be remembered, in the Egyptian war of 1882, and attempts of the same kind have been made during the present war in which we thought it was universally admitted that the medical arrangements and the conduct of medical officers have been admirable. We are glad to see that Mr. Wyndham, in reply to Dr. Farquharson, elicited from the Under Secretary for War the other day in the House of Commons the most satisfactory reply. Lord Roberts had telegraphed that there was no real foundation for reports reflecting on the hospitals at the Cape. He was perfectly satisfied with all arrangements for the reception and the treatment of the wounded, but the quality of the cooking was indifferent for the first week. Nothing more than this can be complained of and this was rectified as soon as possible. Sir Redvers Buller says: "One of the Natal papers is attacking the management of the military hospitals, and as some of the false and ridiculous statements may cause anxiety at home I think it right to say that Mr. Treves assures me that there is no possible ground for complaint and that I may rest satisfied that all the medical arrangements are completely satisfactory to him. I pressed him if he could suggest improvement, and he said he could not. I have given the matter every consideration and can only express my admiration of the arrangements made by Colonel Gallwey and the Royal Army Medical Corps, and Mr. Treves assures me that he entirely agrees with me."

In reference to some allegations that had been made about another hospital, after the matter had been carefully investigated by a court of inquiry, Sir William Stokes stigmatised the charges as false and cruel. The military hospitals are throughout working well and we are assured that the medical officers—the military and the civil element alike—are performing their duties with great zeal and devotion and harmoniously coöperating to the advancement of one end only—viz., the relief and comfort of the sick and wounded by every means in their power. It is but right that the public, and especially those who have their relatives and friends under treatment, should know this. There is no stint of anything that care and forethought can supply. It is gratifying to know that our success in hospital and medical administration in modern war has been progressive and that the measure of this progress has never been greater than on the present occasion.

There is much of that scourge of modern war, enteric fever, present in South Africa, as may be seen from the returns of fatal cases; and the prevalence of this disease, as might have been expected under the circumstances, is most marked at Ladysmith. Dysentery and other less fatal forms of fevers and occasionally respiratory diseases make their appearance, but the British force in the field as a whole is healthy. The climate is beautiful but treacherous at this season, owing to its being hot by day and chilly at night and in early morning, and this predisposes to dysentery, but there is happily very little dew. The air is pure and wounds and surgical cases do well in South Africa. Altogether it may be said that the theatre of war is in a healthy region, that the supplies provided for the army in the field are good, and that our soldiers are well clad and fed—although this cannot, we fear, be said of the feeding of those in the besieged garrisons. As our readers are aware, large bodies of troops with the necessary hospital accommodation are leaving this country every week and Lord Roberts must by this have a big force at his disposal. In the additional estimate for £13,000,000 we notice that £70,000 are to be appropriated to the medical establishment vote. The original estimate for pay and allowances of this establishment was £305,800. This was supplemented on Oct. 17th by £50,000, so that the present estimate brings the total to £425,800.

With regard to the Government's scheme for enlarging the army there is to be a considerable addition to the Regular Army and the Militia, the Yeomanry will be gradually turned into mounted infantry, and the Volunteer force is to be further developed and more fully equipped. This will, of course, necessarily entail a large and corresponding addition to the military medical services of the country.

The Imperial Yeomanry Hospital: Inspection of Personnel by The Prince of Wales.

After inspecting the Imperial Yeomanry at the Albany Barracks on Friday morning, Feb 9th, His Royal Highness the Prince of Wales paid a visit to Devonshire House for the purpose of inspecting the *personnel* of the Imperial Yeomanry Hospital. Besides the Duke and Duchess of Devonshire, among those present were Princess Louis of Battenberg, Lady Georgiana Curzon, Lady Chesham, the Countess of Warwick, Viscountess Valentia, and many of the ladies of the committee of the Imperial Yeomanry Hospital Fund. Sir Nigel Kingscote was in attendance on the Prince of Wales, and there were also present General Trotter, Surgeon-General Jameson, Director-General of the Army Medical Staff, and Surgeon-General Muir, A.M.S. The guests were received by the Duchess of Devonshire at the entrance to the ballroom at the head of the grand staircase, after which the men of the St. John Ambulance Corps were paraded in the ballroom and inspected by the Prince, who addressing them said: "I am very glad to see you all here to-day and I know you will all do your duty. I hope you will have a good passage out and a safe return home in good health." Cheers were then given for the Prince and Princess of Wales. The nurses were afterwards introduced to the Prince of Wales who briefly conversed with some of them. All the medical staff were also presented to His Royal Highness. On Saturday, Feb. 10th, Colonel A. T. Sloggett, R.A.M.C., the military commandant and principal medical officer of the Imperial Yeomanry Hospital, with Mr. Fripp, M.V.O., the chief civilian medical officer, left Waterloo for Southampton and the following members of the medical staff left Waterloo on Monday, Feb. 12th: Dr. J. W. Washbourn, Mr. Raymond Johnson, Mr. F. Newland-Pedley, Mr. L. V. Cargill, Mr. H. A. Ballance, Mr. W. Turner, Mr. J. F. Hall-Edwards, Mr. W. C. G. Ashdowne, Dr. J. B. Christopherson, Dr. Andrew Elliott, Dr. H. W. Saunders, Mr. L. E. C. Handson, Dr. H. W. Bruce, Mr. A. P. Parker, Mr. G. E. Richmond, Dr. R. T. Fitzhugh, and Mr. Barclay Black. The following gentlemen who are accompanying the staff of the hospital as dressers went also: Mr. J. Atkins, Mr. A. Ayre Smith, Dr. C. W. Breeks, Mr. A. de V. Blathwayt, Mr. D. J. Greenfield, Mr. M. B. Hay, Mr. A. Pearson, Mr. A. C. Ransford, Mr. Owen Richards, and Mr. E. N. Thornton. On both occasions there was an enthusiastic demonstration. The medical men for the base hospital have now all left England and arrangements are being made with regard to the field hospital. In a circular signed by Lady Beatrice Chesham and Lady Georgiana Curzon the following passage occurs:

> When we think of the valuable lives that will be risked, it is surely most important that they should be provided with full hospital accommodation complete with every modern appliance and comfort. To carry out this scheme a Ladies' Committee is being formed and we ask all to respond liberally to our call. American ladies have fitted up and despatched the hospital ship *Maine*. Cannot English ladies and—may we suggest it?—in conjunction with those directly connected, by their great properties, with South Africa, fit up and despatch to the front a most complete field hospital for our brave Yeomanry, for whom we believe no special medical provision has yet been made?

Further funds are urgently needed to maintain the field hospital and bearer company. Anyone willing to support or assist this scheme is invited to communicate with or to send a subscription to Viscount Curzon, M.P., 20, Curzon-street, London, W., or to Ludwig Neumann, Esq., 11, Grosvenor-square, London, W.

Netley Hospital. The War and the Great Base Hospital of the Army.

The present staff of Netley Hospital consists of the principal medical officer, Colonel W. J. Charlton, and his two secretaries, the senior of whom is in command of the corps at Netley and the junior the adjutant; of an officer in charge of each division of the hospital—Lieutenant-Colonel W. E. Webb, M.D. Aberd., being in command in the medical division, with a staff of one major and one subaltern of the Royal Army Medical Corps, one surgeon-captain of the Militia.

Medical Staff Corps, and one civilian serving under him; and Major W. Dick, M.B., F.R C S. Edin., of the surgical division, with one major, one captain, and one subaltern of the Royal Army Medical Corps, one subaltern of the Militia Medical Staff Corps, and four civilian surgeons as his assistants. Serving under Miss Norman, the lady superintendent of nurses, are 11 nurses, mostly belonging to the Army Reserve of Nurses, while the men of the Royal Army Medical Corps who have been sent to the front are replaced for the most part by militia orderlies.

As may easily be imagined the war in South Africa has brought a busy time to all the departments of the great base hospital of the army—the Royal Victoria Hospital, Netley. While the medical and surgical divisions of the hospital are already growing full of the sick and wounded which arrive in a steady stream in transports from South Africa the other departments of the great institution are no less busy—indeed, are working at high pressure. In the laboratories of the Army Medical School important work is being done in connexion with the war. On the hygiene side, presided over by Colonel J. Lane Notter, M.D. Dub., and his assistant Major W. Horrocks, M.B. Lond. Analyses of food stuffs are of frequent occurrence and the testing of the properties of filters for the front has occupied much attention—those recommended being filters on the Pasteur-Chamberland principle, offered to the Government by Messrs. Slack and Brownlow, who have expressed their ability to supply as many as 1000 within a very short period. On the pathological side, under the guidance of Professor A. E. Wright, M.D. Dub., large quantities of anti-typhoid vaccine are being manufactured and despatched both direct to South Africa and to the different transports as they leave the ports, while during the last few days 500 doses of diphtheritic serum were suddenly requisitioned and despatched to South Africa.

In the divisions of the hospital about 1000 men have been admitted from South Africa, of whom 280 have already been discharged to convalescent homes or on furlough, or to return to the front—a privilege for which a large number of the men are anxious. A few days ago there were from the front 357 medical and 329 surgical cases in hospital, while the pressure in the latter division has already been sufficient to necessitate that wards in the B Section of the medical division should be placed at the disposal of officers doing duty on the surgical side. For obvious reasons the greater number of the men who are admitted are convalescent or have made considerable progress on the road to recovery. The larger number of men are able to march from the railway-station to their wards, and it is only on the medical side that there are at present many cases of great gravity. In this division it is felt that the strain which the campaign must of necessity bring can scarcely be said to have commenced, but it is expected that when Kimberley and Ladysmith are relieved the number of serious medical cases will be very great indeed and will tax the resources of the hospital to its utmost. The diseases which have struck down our soldiers in South Africa are those which were expected from previous experience gained in our campaigns in tropical and semi-tropical countries—viz., sunstroke, dysentery, rheumatism, and enteric fever. We give them in the order of their importance as has been so far revealed by the present campaign. On the surgical side of the hospital we are struck by the small size of the wounds made by the Mauser bullets, by the excellent way in which the wounds have for the most part healed, leaving scarcely any scars, and by the extraordinarily small amount of damage to organs and to life which wounds in what have hitherto been regarded as vital parts, have *often caused*. In one case—that of Private Coulter of the Scots Guards—a bullet entered on the left side of the neck and passed out near the axillary border of the right pectoralis major muscle. From the history of the case the œsophagus must have been wounded and there is now an aneurysmal varix of the lower part of the right carotid and internal jugular vein, yet with the exception of a dilated right pupil and the physical signs of the varix the man now appears to be in good health. In another case—that of a man named Coutts, who has now been sent to the Duke of Richmond's convalescent home—the ball passed across the neck behind one carotid sheath and in front of the other, fracturing the thyroid cartilage. In this case the voice has not been lost. Private Umney, who is now quite convalescent, was shot by a Mauser bullet which entered above the outer part of the left eyebrow and traversing the centre of the face came out through the right malar bone. He was wounded at the Modder river and is now perfectly well save that he suffers from diplopia and has lost the sense of smell. Lodged bullets have not been frequently met with, and there is one patient in the hospital with a round ball embedded in the head of the humerus. A sergeant in the King's Own Light Infantry has a ball lying on the right side of the diaphragm about two inches from the spine which now causes him no inconvience. He received his wound at Graspan. The entrance wound was in the second right intercostal space, and he suffered from hæmorrhage from the mouth for five days. In both these cases the bullets have been localised with the x rays.

Another circumstance which at once strikes the surgeon is the large number of men who have been sent home after perforating wounds of the thorax, abdomen, and even of the skull, who are now convalescent. In no case of perforating wound of the abdomen so far admitted to the hospital was laparotomy performed in South Africa. This class of cases is well exemplified by that of Driver Cameron of No. 7 Field Battery, who was shot at Colenso while trying to recover the guns and bring them out of action. In his case the ball entered in front of the head of the right humerus and passed out on the left side of the fifth dorsal vertebra. He suffered from severe bleeding from the lung. In the case of Private Clark who was shot at Colenso at a distance of about 200 yards the ball entered just below the left sterno clavicular articulation and came out well above the inferior angle of the scapula on the same side, but as his arm was raised at the time the latter bone was not touched. Private Taylor of the 2nd King's Own Light Infantry was wounded in the abdomen, the ball passing in at the margin of the right ribs and out in the loin near the margin of the right kidney. In the case of Private Kerr the ball passed through the pelvis, entering above the right pubes and passing out on the inner side of the right tuber ischii. There is no history of bladder trouble. In one patient a ball passed through the penis, scrotum (wounding the testicle), and thigh, emerging in the right buttock; in another case, that of a sergeant of the Grenadier Guards, the ball passed through the left testicle and right thigh. Wonderful have been the escapes of the great blood-vessels. In Private Smith of the 2nd Seaforth Highlanders a bullet entered behind the right external carotid vessels behind the angle of the jaw and came out through the left side of the inferior maxilla, removing the first lower bicuspid. Here the ball, of course, passed through the tongue and the man almost died from hæmorrhage, but all that now remains are the scars and a very slight occasional lisp. On several patients marks have been observed on the skin which can only be explained by the theory that they are due to scorching by bullets in their flight and in one case—that of a spent ball—to a burning effect on its lodging against the skin.

While every care and attention are being given inside the hospital to those who have already arrived great preparations are being made for the easy transport and further accommodation of those about to come home for treatment. As far back as the year 1875 Her Majesty the Queen made inquiries as to the method of transport of patients to the hospital and suggested that the railway line might be continued from the invalid station at Netley to the actual precincts *of the hospital buildings*. On one of her visits last year after the Omdurman campaign the Queen again made similar inquiries, which resulted in the present activity in the engineering department of the staff, and in the continuation of the line from the old invalid station to the back of the hospital in close proximity to the military chapel. The new line, which is about three-fourths of a mile long, will be completed by the end of March provided that open weather prevails and will do away with the necessity of wheeled transport; for the new station will partly occupy the site of the present road at the back of the hospital and from it the patients will be moved into the lower corridor and to the left under a covered way.

As the maximum number of patients which the hospital buildings are able to accommodate is between 1000 and 1100 steps are being taken to provide for the convalescent men in huts outside *the hospital*. The *pattern of* hut selected is known as the "Dœcker hut" and of these 30 of different sizes have been placed at the disposal of the Government by the Red Cross Society and are now being erected under the orders of Captain Stevens, R.E. The huts are of German or Austrian manufacture and some of those now erected are said to have been intended originally for the Russian Government. The average cubic space in the huts is about 7800 feet and they are intended to house on an average 10 men each or a total of 300 or rather more. The walls are made of a double layer of felted paper with a cavity of three-quarters of an inch between, with wooden supports, and are said to be fireproof inside and waterproof outside. The huts are constructed with sloping roofs and are well lighted and ventilated. Those who know them, however, say that they are cold in winter and very hot in summer, but in order to decrease the temperature during the latter season portions of the sides are made to lift up and thus form shaded open doors. The huts are to be warmed with the "Magnet" slow combustion stoves, of which there are to be two in each. The floor of each hut, which is made of wood, is to be covered with linoleum to prevent draughts and is raised off the ground about a foot, but the cavity thus formed is to be boxed in, which will increase the warmth in cold weather. It is considered probable that it will be necessary to cover each hut with a canvas fly during the hot summer months. Each hut is provided at one end with a small separate room in which there is a dry earth closet and it is intended to erect tubs containing sawdust to act as urinals, the contents of which will be daily destroyed by the cremator. These huts are being erected on the high ground at the back of the hospital and placed in three rows of 10 each, a space of 30 feet in each direction being left between the huts, with a central road of 60 feet in width. Gravel paths have been laid in all directions between the buildings and the camp already presents a smart appearance. The huts have one great advantage, viz., that they are portable and fairly easy to erect by trained men who understand them, but the cost of the latter process is rather considerable. The interior decoration of the huts has been undertaken by rs. Stevens, who is being aided by many local friends, and he wives of members of the Netley military staff.

While activity thus reigns in the hospital and its vicinity much useful work is being done by the officers' wives in providing for the families of the men sent to the front and for the near relatives of the seriously wounded men who are summoned to Netley to be near the sufferers. A very perfect organisation exists for these purposes in the Soldiers and Sailors Families Association. Nor has the comfort of the men of the Royal Army Medical Corps who have been sent to the front been forgotten. A fund was started by Mrs. Charlton, the wife of the principal medical officer, to provide extra clothing and comforts in the shape of tobacco, pipes, &c., for the men and has been well responded to. On Saturday last the first consignment of these goods was sent out to South Africa and we are glad to hear that further supplies will be sent out at intervals by the larger London committee, of which a notice has appeared in our columns, and which will ably second and further develop the movement which Mrs. Charlton and the ladies of the Netley staff so ably inaugurated. The number of men of the corps with the eight divisions already mobilised which have arrived or are now on their way to South Africa is some 3000. The men with the fourth division are locked up in Ladysmith and will have to wait, we fear, for their presents from home which are now on their way to the men with the first three and fifth divisions, while the boxes for the men with the divisions more lately sent out are soon to follow. We hear that a philanthropic gentleman in the north of England has sent a quarter of a pound of tobacco and a pipe to each man of the corps in South Africa as an independent present and that a large part of the consignment has already been received.

The Army Medical School shall open on March 1st instead of as hitherto on April 1st, and if the war be not brought to a speedier termination than is at present anticipated the young medical men so soon to commence their military career may find themselves at the front immediately to replace the waste inevitable to such a campaign as the empire is now involved in.

ROYAL VISIT TO NETLEY.

On Tuesday, Feb. 6th, H.R.H. Princess Christian paid a visit to the sick and wounded soldiers under treatment in the Royal Victoria Hospital. The sun was shining brilliantly when the Princess, accompanied by her daughter, Princess Victoria, and attended by Colonel Donald Brown, Equerry in Waiting, crossed over from Cowes to the mainland on board the Royal yacht *Alberta*. The yacht was brought to anchor off Netley pier, a steam launch being employed to land the Royal party. At the head of the pier the Princess was met by Colonel W. J. Charlton, Principal Medical Officer, Netley, and by Colonel W. B. Creagh, Assistant Adjutant-General. After the formal introductions the party were escorted to the base of the pier, where they entered the Hon. Mrs. Eliot Yorke's carriage and drove with her to the main entrance of the hospital. Here the Princess was met by Miss Norman, the lady superintendent of nurses, and by Lieutenant-Colonel W. E. Webb, R.A.M.C., Major W. Dick, R.A.M.C., and other members of the present military and civil staff of the hospital. Both the medical and surgical divisions of the hospital were in turn visited, the former being under the command of Lieutenant-Colonel W. E. Webb, R.A.M.C., and the latter under that of Major Dick, R.A.M.C., who respectively explained what was necessary to the Royal visitors. The convalescent patients were drawn up in line in the corridors and were spoken to by the Princesses as they passed on their way to see the more serious cases in the wards. Each of the divisions of the great hospital is divided into A and B sections, and all in turn were visited. The surgical patients were shown to the Royal visitors first, the Princesses going from bed to bed, speaking words of comfort and sympathy and distributing a profusion of beautiful flowers which had been specially sent by Her Majesty the Queen and which were brought off the *Alberta* b some of the crew. The Princesses showed much interest in th young drummer, John Dunn, of the Royal Dublin Fusilier who was acting as bugler at Colenso, and who, when h right arm was disabled, transferred his bugle to his oth hand and refused to quit the fighting line. Among t patients were several men who have been recommended the decoration for distinguished service in the field. On day on which the Princesses visited it the hospital contai over 650 men from South Africa besides some 150 men f other parts of the Queen's dominions. The Royal p remained in the hospital for about an hour and a half, at end of the visit returning to the pier and re-embarkin Cowes.

HOSPITAL ACCOMMODATION FOR THE SICK AND WOU
FROM SOUTH AFRICA.

DENTAL SURGEONS FOR THE ARMY IN SOUT

BY MR. F. NEWLAND-PEDLEY,

DENTAL SURGEON TO THE IMPERIAL YEOMANRY HOS

When the staff of the Imperial Yeomanry H being appointed I was asked by Mr. Fripp if I v I said "Yes," and have devoted the interval to suitable equipment. The difficulty has been to de lines the appointment could best be held. In ro there will be an army of 160,000 troops in th large percentage of head injuries are reporte be explained by the peculiar nature of in which fighting under cover is the lea A dental surgeon would be very usefu sultant, especially in cases of fractured his services are not less required by patients who must be suffering from neuralgia and diseases of the jaw consequent upon a in a climate where sudden changes of t common. I read that at the Modder river the plaints about dental suffering than about ty dysentery. One feels compelled to face the can one dental surgeon do for an army ? that he can do is to go prepared for any his lot, leaving the extent of his duty to shape its own course.

With this determination I went to one of the chief instrument makers in the dental branch of the trade and bought everything that I thought might be needed for three operators engaged in the work of ordinary dental practice. I purchased two operating chairs and took a third from home. I also provided myself with the tools, appliances, and materials that might be required by two or three dental mechanics in making splints and mechanical contrivances for cases of mandibular and maxillary fracture. Messrs. Ash and Sons treated me with very great liberality and let me have everything which I required, excepting precious metals, at a discount of 50 per cent. Then arose the question of obtaining a continuous supply of nitrous oxide gas. I wished to take 6000 gallons with me. There is rather a strong prejudice in the shipping trade against carrying the iron cylinders that contain the liquid gas; some firms seem to be more afraid of laughing gas than of ammunition. Even where the matter of transport was satisfactorily settled there was the heavy expense of the bottles to be considered, but Messrs. Ash and Sons solved the difficulty by lending me the bottles. The Imperial Yeomanry Hospital undertook the cost of gas, oxygen, and anæsthetic apparatus. By the time my things were packed there were only 48 hours before the *Majestic* was to sail, so I had to take everything as my personal luggage. I had to send it in a pantechnicon van to Waterloo Station. There were nearly 20 parcels weighing about two and a half tons.

Since I accepted the appointment I have been arranging for a supply of skilled assistants if they should be required. About 15 of my pupils have volunteered to sail at short notice if wanted. Each of them will take his own set of instruments and dental engine. They would sign for six months certain, expecting a free voyage out and home, with maintenance within the hospital to which they may be attached. Some are qualified men, some are students, but they can all do a day's work in the conservation room or in the laboratory, and can, under instruction, make any splints and appliances wanted. The Royal College of Surgeons of England have consented to recognise six months' service in hospital at the seat of war as the equivalent of the ordinary curriculum, provided that the student shall produce satisfactory evidence concerning the manner in which the time has been spent.

From the foregoing rapid sketch it will be seen that with my strong reserve of skilled assistants I hope to meet the requirements of the Imperial Yeomanry Hospital, and if it be desired to send small efficient contingents of skilled assistants to the great camps and hospitals in South Africa. The matter beyond this point must depend on what the authorities wish to be done. F. NEWLAND PEDLEY.

AMONGST THE BOER WOUNDED AT ORANGE RIVER:

NOTES BY MR. S. W. F. RICHARDSON, M.B., B.S., B.Sc. LOND., F.R.C.S. ENG.,

CIVIL SURGEON TO HER MAJESTY'S FORCES IN SOUTH AFRICA, ATTACHED TO THE CAPE FIELD HOSPITAL, ORANGE RIVER.

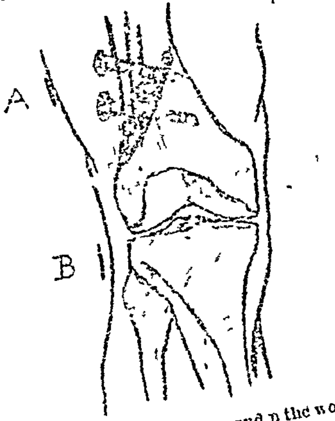
Amongst the Boer wounded admitted into the Cape Field Hospital under the command of Major J. H. Greenway, R.A.M.C., stationed at Orange river, were many cases of unusual interest, especially owing to the fact that they were examples of gunshot wounds caused by Lee-Metford bullets. Amongst those who came under my care were wounds of almost every region of the body. In describing the details of the following cases I would mention that their chief interest lay in that they were treated in a field hospital and consequently the surgeon had to combat all the difficulties necessarily following upon operations performed under such circumstances. We possessed at Orange river, however, the great advantage of having at our disposal the constant advice and assistance of Mr. Makins, whose skill and judgment were freely placed at our disposal.

Besides the following cases, which are described in detail, were many other interesting cases of gunshot wounds, including three fractures of the left of the femur, one fracture of the humerus, one fracture of the clavicle, three fractures of the radius, and two fractures of the tibia, besides four cases of penetrating wounds of the knee joint without fracture. There were also three interesting cases of penetrating wounds of the abdomen—in one patient the bullet passed transversely through the right lobe of the liver—and all three are satisfactorily recovering.

CASE 1.—A Transvaal Boer named Wergotini, aged 36 years, was shot at Modder river on Dec. 8th, 1899, and was admitted into the Cape Field Hospital at Orange river the next day. He did not remember anything before the operation was performed, but a first field-dressing was applied to the wound when he arrived at Orange river. On admission he was semi conscious, but easily roused. His pupils were equal and acted to light. There was much bruising about the supra-orbital regions and slight sub-conjunctival ecchymosis, but no paralysis. The temperature was 99° F. The aperture of entrance of the bullet, which presumably was a Lee-Metford, was situated three inches above the centre of the left eyebrow; it was circular and of about the size of a threepenny-piece, and its margin was somewhat inverted. Around the skin aperture a slightly larger opening in the bone could be felt with a definite margin. The aperture of exit was situated three inches above the outer end of the right eyebrow and was slightly larger and more ragged than the aperture of entrance, and the underlying bone could be felt to be much fragmented over a small area in this region. From both openings, especially from the exit wound, escaped a blood-stained discharge mixed with flakes of brain-matter. No marked depression of bone could be felt at either opening, each of which was quite clean and not inflamed. The operation was performed on Dec 9th. Chloroform was administered and a semilunar periosteal flap was turned down, with its base at the eyebrows, the flap including the whole frontal region of the scalp. The apertures in the frontal bones were thus disclosed. The aperture of exit was twice the size of the aperture of entrance and there were a few loose pieces of the external table of the skull at its edges, and a fissure ran from this aperture towards the roof of the right orbit. The aperture of entrance just admitted the little finger and was very cleanly cut. The edges were slightly irregular, but no fragmentation of the internal table could be discovered. The dura mater at both of the openings showed a deficiency about the size of the apertures in the bone and a definite bruised track in the brain matter between the two openings could be easily made out. The brain pulsated around both apertures. The bone between the openings was normal. There was slight bleeding from a meningeal vessel at the exit aperture which was easily stopped by ligature, but there was no great blood extravasation. The loose fragments of bone were removed and the edges in the apertures in the bone smoothed off with gouge forceps. The whole wound area was then cleaned with carbolic lotion, the apertures in the scalp were excised and sewn up, the large flap was replaced and sutured in position and cyanide dressing was applied. The progress of the patient was uneventful. He gradually became more conscious and complained of headache for the first few days following the operation. The temperature did not rise above 100°. When the wounds were dressed on the 18th they were found to have healed, and on the 28th he was quite well. The brain could be felt pulsating over the apertures both of entrance and exit, especially over the latter. On Jan. 13th, 1900, the patient was transferred as a prisoner to Cape Town. On the evening of the day of the operation, owing to a very heavy downpour of rain, the patient's tent was rapidly flooded, and without waiting for assistance he waded ankle-deep in water with his coat over his head to drier ground. This patient is one of seven patients with penetrating gunshot wounds of the skull who have been successfully operated upon at Orange river.

CASE 2.—A Free State Boer, named P. Nel, aged 39 years, was wounded in the battle at Belmont in the lower third of the right thigh. He was admitted into the Cape Field Hospital two days later—i.e., on Nov. 25th—having a fracture of the femur. The bullet, a Lee-Metford, entered about three inches above the external condyle and was felt close under the skin over the external tuberosity of the tibia. It was cut down upon by Surgeon-Major Cox, of the Cape Volunteer Medical Staff, and removed. Both wounds healed readily under antiseptic dressings, but great difficulty was experienced in getting the two fragments of the femur into good apposition, so much so that on Dec. 8th operative measures were suggested by Mr. Makins as the only means of obtaining a good result. At this date both wounds had practically healed and an oblique fracture, as shown in the diagram, was felt. There was shortening of the limb to about three inches, but the knee-joint [illegible] to [illegible]
The lower end of the upper

ose under the skin on the outer side of the knee. The atient was a strong, healthy man with no signs of organic isease. It was consequently decided to expose the seat of he fractures and screw the fragments together with Lane's crews, which Mr. Makins kindly supplied. On the 8th chloroform was administered by Dr. Pershouse (civil surgeon) and an incision from four to five inches long was made parallel to, and in front of, the biceps tendon.



A marks the wound of entrance and B the wound of exit.

The lower end of the upper fragment was thus exposed, projecting through the vastus externus muscle, while a large strip of this muscle intervened between the fragments of bone. This intervening strip of muscle was divided and after removal of a small piece of the upper fragment of the femur the fractured ends were brought into good apposition. The bone was then drilled and two screws were inserted which held the fragments well together. Owing to the removal of a longitudinal piece of the upper fragment the lower screw could not closely approximate the two fragments. There was no comminution of bone at the seat of fracture and very little fissuring at the ends of the fragments. Care was taken not to unnecessarily strip off the periosteum from the bone. Deep sutures were then inserted and the edges of the wound were approximated. A gauze drain was inserted at the lower end of the wound and cyanide dressing and a Lister long outside splint was applied. Mr. Makins and also Dr. Crispin, civil surgeon, kindly assisted me at this operation. The progress of the patient was satisfactory. The wound was dressed on the day following the operation and the gauze drain was removed. The patient's temperature on this day was 99° F. and on the 12th it was 100° There was no pain. On the 14th the wound was dressed and was found to have practically healed by first intention, but over the situation of the aperture of entrance of the bullet there was a fluctuating swelling which was opened and an ounce of broken-down clot was evacuated. On the 18th the temperature was 101°. The wound was syringed out, the discharge being purulent. The condition of the knee-joint was normal and there was only very slight pain. A bracketed long outside splint was applied. The wound was now dressed every day. The cavity gradually contracted. The fracture was examined on Jan. 13th, when it was fixed in plaster-of-Paris, and was found to be firmly united and in good position with practically no shortening of the limb.

CASE 3.—A young man named Du Toit, aged 19 years, a Free State Boer, was shot in the back at Graspan battle and lay on the field for 12 hours before he was removed. He was then taken to Modder river and on the next day he was taken to Orange river. Before admission he suffered from severe hæmoptysis with cough and pain in the chest. When first seen at Orange river on Dec 3rd the patient was found to be suffering from a gunshot wound of the left side of the chest with lodgment of the bullet. The aperture of entrance was situated an inch to the left of the second lumbar spinous process and an inch below the top of the last rib on the left side. The track appeared to pass in an upward direction. There was dulness over the left chest to the level of the second rib, with loss of breath sounds and vocal fremitus over the area, pointing to a condition of hæmothorax. The heart apex could not easily be made out, but appeared to be displaced pulsation could be easily felt in the fourth right interspace close to the sternum. The pulse was 110 and the temperature was 102° F. There was no fracture of the ribs; the right side of the chest was normal, and there was no hæmaturia. There was slight cough with blood-stained expectoration and some dyspnœa. The patient was a thin, anæmic, large-boned youth. The entrance wound rapidly healed under a collodion scab, but the cough and dyspnœa, together with an almost uniform temperature of 102° in the evenings, combined with the physical signs in the chest, made us decide to empty and drain the left pleura. Consequently, on the 13th chloroform was administered by Dr. Pershouse and two inches of the eighth rib on the left side in the posterior axillary line were resected and the pleural cavity was opened, when five pints of dark-red, grumous, inoffensive fluid with a few clots were evacuated. The lung was found to be considerably collapsed and a track appeared to pass between the two lobes towards the spinal column, and on the insertion of a probe it seemed likely that the bullet was firmly fixed near this situation. Nothing further was done beyond a drainage-tube being inserted and cyanide dressings applied. On the following day the patient was much relieved by the operation and the heart was then easily felt beating in the fourth right interspace near the sternum. The temperature was 101° F. On the 16th the wound was dressed and the drainage-tube was removed. Considerable discharge was found upon the dressings, which were, however, quite sweet. The temperature was 101·4° F. On the 20th the temperature had declined to 99 8° F. and the wound was rapidly healing. The lung was expanding; there was some slight dulness over the left base. The patient was much improved. On the 31st the wound was practically healed. Breath sounds could be heard to the base of the left chest. There was no dulness. The temperature still rose to about 101 2° every evening. The patient's chest had been x-rayed, but the position of the bullet could not be localised. This examination was kindly performed for us by members of the New South Wales Medical Corps of which Colonel Williams was in command. On Jan. 4th the patient developed some impaired resonance with tubular breathing on the right side of the chest just below the angle of the scapula. This, however, rapidly cleared up and on the 13th the patient was quickly convalescing, but the heart still remained displaced to the right side.

CASE 4.—A Boer named Fouri, aged 41 years, was shot in the right knee at the battle of Belmont. The bullet entered by a very small opening at the lower and inner part of the popliteal space and gained an exit through the centre of the patella, causing a transverse fracture of the bone, and emerged by an irregular wound considerably larger than the wound of entrance. The patella was not comminuted and there was about two fingers' breadth interval between the fragments. The joint was considerably swollen. After a few days' rest upon a MacIntyre's splint this swelling diminished, the fragments of the patella were almost approximated, and the wounds healed. Consequently the knee was immobilised in plaster of Paris with strapping applied to keep the fragments of the patella together. This splint was kept on until Jan. 10th, when upon removal of the splint the fracture was well united. The joint being normal the patient was allowed to walk about.

CASE 5.—A Free State Boer named Fonchee, aged 34 years, was shot at Modder river on Nov. 28th, the bullet entering the inner side of the left knee on a level with the upper border of the patella and gaining exit close to the inner side of the patella, which latter it slightly splintere at its edge. When first seen at Orange river on Dec. 3r the wound in front of the patella was septic and there we some swelling and distension of the joint. The temperatu was 101·8° F This condition of the joint did not impro under rest and antiseptic treatment of the wound; theref on the 7th the joint, which was then considerably disten and painful, was opened by an incision on the i side of the patella and about four ounces of turbid se fluid were let out. The joint was then washed with a carbolic lotion (1 in 10) and the inc sewn up. The limb was placed on a MacIntyre's and dressings were applied. The condition of the gradually improved and the wounds healed, so that 27th a plaster-of-Paris splint was applied. Thi removed on Jan. 13th, when the joint was found quite normal in character with no pain and ver swelling. The patient was then transferred as a prisoner to Cape Town.

CASE 6.—A Scandinavian Boer named Van Ekem was shot in the abdomen on Dec. 11th at Magersfontein. He lay on the field for 12 hours and the wound was then dressed with first field-dressing. He was then removed to Modder river where he remained until the 14th, when he was taken to Orange river. Before arrival at the latter place he was continually sick and had great pain in the abdomen which was considerably swollen. The bowels acted soon after the receipt of the wound, but there was no passage of blood either by the bowel, by the bladder, or by the stomach. On admission to the hospital the patient was found to be a thin, anæmic man with an anxious expression. He lay with his knees drawn up. There was considerable distension, especially in the epigastric region, and tenderness, especially in the right loin. The wound of entrance of the bullet was very small and was situated in the left loin four inches from the fourth lumbar spinous process and one inch below the tip of the last rib. The wound of exit was somewhat larger than that of entrance and was situated over the edge of the costal margin on the right side of the abdomen in about the mid-axillary line—i.e., about the level of the cartilage of the tenth rib. No fracture of rib was felt. The chest was quite healthy. In the right loin there was dulness to percussion which extended in front to the right semilunar line; this dulness did not appear to shift with the movements of the patient. The pulse was 100 and the temperature was 100·8° F. Liver dulness was present, but the chest was normal to examination. It was decided to watch the patient and administer a dose of magnesium sulphate. This produced a complete evacuation of the bowels, and the patient considerably improved, the distension becoming less and the sickness stopping; but the temperature still remained at about 100° F. in the evenings. The dulness on the right flank also remained, but diminished somewhat in extent till about the last week in December, when a definite, tender, and painful swelling was detected close to the costal margin, opposite and deep to the wound of exit of the bullet. Consequently on the 31st chloroform was administered and an incision was made parallel to the costal margin and close to the wound of exit which, as well as the wound of entrance, had by this time quite healed under a collodion scab. On deepening the incision the attachment of the tenth rib to its costal cartilage was exposed and a fracture of this rib was found at half an inch from its cartilage end. The fractured ends of the rib were resected and the intercostal muscles and the attachment of the diaphragm to this rib were cut through. On doing this about four ounces of thick inoffensive pus were evacuated from a cavity whose floor was apparently formed by the surface of the liver. The cavity was circumscribed and as far as could be made out without danger of opening the general peritoneal cavity it did not pass in a downward or inward direction. A drainage-tube was therefore inserted and antiseptic dressings were applied. This operation completely relieved the pain and the wound was washed out and dressed daily. One week after the operation the patient began to have severe pain in the right iliac fossa and rigidity and impaired resonance in the same locality, and his temperature, which had become normal after the operation, again reached 100° F. in the evenings. On Jan. 9th, therefore, fearing that pus was tracking behind the peritoneum into the iliac fossa, an incision was made under chloroform just internal to the anterior superior iliac spine and deepened to the peritoneum, which latter was raised from the iliac fossa towards the pelvic brim. No pus was detected. A drainage-tube was inserted and the wound sewn up and dressed separately from the incision made at the first operation. The patient was relieved of his pain by this operation and he no longer suffered from the severe pain running down the right thigh which he did before the operation. The drainage-tube was left in for two days and was then removed and the wound was carefully dressed, and when dressed again on the 14th it was healing without reaction. The drainage-tube in the wound made at the first operation was now shortened as the discharge from this wound had considerably diminished. The rest of the abdomen was normal in character and the bowels were acting regularly. The patient was well on the way to convalescence when I gave up charge of his case on the 14th. This case is an example of several similar cases of penetrating gunshot wounds of the abdomen in which the perforation of the bowel, if present, is situated in the large intestine and thus probably extra-peritoneal, and where the results produced by the perforation become localised. These cases give extremely good results under expectant treatment.

Other cases of penetrating gunshot wounds of the abdomen occurred in which the perforation if present was situated in the small intestine and in which the result produced was a rapidly progressing general peritonitis from extravasation of the intestinal contents over the general peritoneal cavity. Patients in these cases must, of course, to ensure success be treated as early as possible after the receipt of the injury, otherwise no satisfactory results can be expected.

Orange River, Jan 15th.

(FROM OUR SPECIAL CORRESPONDENT AT THE BASE.)

Part of a sanitarium situated at Claremont has been taken over for the treatment of convalescent officers discharged from the various base hospitals. Claremont is a suburb of Cape Town. The sanitarium is complete in all particulars, including an admirable system of electric and other baths, trained masseurs, and a gymnasium. Each officer has a well appointed bedroom furnished with electric light, and there are large verandahs and extensive grounds—everything, in fact, that can tend to hasten the recovery of a patient suffering from wounds or disease. Up to the present some 60 or 70 officers have been sent there, and I need hardly say that it is a great boon to them and a convenience to the staff of our general hospitals, which can thus keep their wards ready for the more serious cases that will be coming down from the front. The letter to the *Times* complaining of the want of attendance, short rations, and maladministration said to exist at the officers' hospital at Wynberg has caused the greatest indignation amongst the officers who have been treated there, and many letters have been received from patients who have recovered and gone to the front denying *in toto* that there was a word of truth in the allegations. Had the authorities of the *Times* taken the trouble to inquire for themselves from any of the officers (of whom there are plenty at home at present) instead of publishing vague insinuations which could only emanate from outsiders suffering from pique at not being allowed to interfere in matters that did not come within their province they would have had ample evidence to convince them that these alleged defects were grossly exaggerated and had no foundation in fact. But I say no more, for, thank goodness, in this campaign the medical authorities can afford to be generous and to ignore "pin pricks."

Several trains bearing patients have lately come down, but the cases have been principally medical ones, as the field and stationary hospitals have been quite able to cope with the results of the scattered skirmishes that have taken place lately. I hear that enteric fever is beginning to become troublesome at the Modder, and we know that it is bad at Ladysmith, but before you get this letter I hope the latter will have been relieved, and the necessary comforts and nursing facilities which will follow in the footsteps of our relieving force will soon alter the state of affairs. I told you last week that the *Majestic* was on the point of leaving with wounded officers and men, and I took the opportunity of going on board on the day of sailing to see for myself the accommodation for the wounded, and from what I saw I hope that if bad luck causes me to be sent home invalided I may be given a passage in a White Star liner. Luxury was not the word for it, and the only grumbler I met with was an officer who had lost his arm and who complained with a twinkle in his eye that he had only been given a £100 state room instead of one quoted for the Atlantic passage at £160. The quarters and accommodation for the men were equally good; and I fancy that there will be no complaints regarding overcrowding as she took home only 13 officers and about 180 men, her usual complement being 250 saloon passengers and from 600 to 1600 third class passengers. The transports *Orient*, *Kildonan Castle*, *Cymric*, and *Nomadic* have come in during the last 48 hours, and have disembarked almost as many sick as we have sent home. Pneumonia seems to be the prevalent disease on board.

Claremont, Jan. 24th.

LITERARY INTELLIGENCE.—Messrs. Churchill are bringing out a new edition of "The Mental Affections of Children," by Dr. W. W. Ireland, published in the summer of 1898.

SICK AND WOUNDED OFFICERS' SURGICAL AND MEDICAL AID FUND.

THE following subscriptions in addition to those already announced have been received:—

	£	s.	d.
Miss A. G. Nobes	5	5	0
Sir W. Thornley Stoker	5	5	0
"A"	5	0	0
"A Lady," per the Rev. H. G. H.	5	0	0
Mrs. Percival Frost ..	5	0	0
In Memory of the late Countess of Lathom ..	5	0	0
F. I.	5	0	0
Miss F. M. Irvine ...	5	0	0

Subscriptions should be sent to Messrs. Coutts and Co, Strand, or to the honorary secretary and treasurer, Mr. Arthur Brodrick, at Hampden House, 61, Green street, W.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Feb. 8th, the senior vice-president, Mr. H G. HOWSE, being in the chair.

Mr. W. H. A. Jacobson of Guy's Hospital was elected a member of the Court of Examiners, and Mr. H. W. Page was elected a member of the Board of Examiners in Dental Surgery.

The Vice-Presidents reported that in pursuance of the resolution of the Council of Jan. 11th they had nominated Dr. W. D. Halliburton, F.R.S., and Dr. E. H. Starling, F R.S., to give evidence before the committee appointed by the Local Government Board to inquire into the use and effects of food preservatives and colouring matters.

The Vice-Presidents reported that Mr. S. Hamilton Cartwright had ascertained that the Charity Commissioners were prepared to consent to the alteration of the Cartwright Trust for the purpose of giving effect to the scheme proposed by the Council, provided that the funds were invested in the name of the official trustee by whom the dividends would be paid to the trustees, who, they suggested, should be the President and Vice-Presidents of the College *ex officio*. The Vice-Presidents stated that they had agreed to this proposal.

A letter was read from Mr. F. Newland-Pedley, F.R.C.S. Eng., stating that he is going to South Africa as a dental surgeon and will greatly need the help of several dental students to make splints and to act as assistants, and asking that the service of such students in the Imperial Yeomanry Hospital may count as part of their hospital curriculum. It was resolved that Mr. Newland-Pedley should be informed that on the production of satisfactory evidence the service rendered by dental students in the Imperial Yeomanry Hospital shall be reckoned as part of the hospital curriculum for a period not exceeding six months in such manner as the Board of Examiners in Dental Surgery may recommend.

It was referred to the Committee of Management to consider and to report to the two Colleges on the recognition of the services rendered by medical students at the seat of war as a part of the hospital curriculum.

A letter was received from Mr. F. Rowland Humphreys, honorary secretary of the Midwives Bill Committee, forwarding a copy of the *Midwives Bill, 1900*. A small committee was appointed to consider the subject and to report to the Council.

A letter was read from the President and General Secretary of the Thirteenth International Medical Congress to be held in Paris, inviting the College to send a representative to the Congress. It was resolved that Sir William MacCormac should be asked to act as the representative of the College.

A letter was read from Sir John R. Paget, Bart, thanking the Council for their resolution of condolence on the death of his father.

THE ANNUAL REPORT (1898) OF THE MEDICAL OFFICER OF HEALTH OF LONDON.

II.

ON a recent occasion[1] we drew attention to certain sections of Part III. of Mr. Shirley Murphy's report, which treats of the administrative action of the London County Council for the protection of the public health. In the present article we shall briefly discuss Part I. of that report, which deals with the vital statistics of the Administrative County of London for the year 1898.

The statistical information which ever since his appointment some 10 years ago Mr. Shirley Murphy has furnished in his successive annual reports differs considerably from that which emanates from Somerset House. For whilst the General Register Office deals of necessity with the question of mortality alone, the county medical officer of health considers in addition the behaviour of the sickness which *leads to that mortality*—as far, at least, as he possesses the means *of so doing*. It is evident, therefore, that in regard *to those* diseases which are most obviously amenable to control by sanitary measures Mr. Shirley Murphy's statistics must be regarded as possessing a value which is unique; and we do not hesitate to repeat the opinion which we expressed concerning some of the earlier numbers of the series, that these reports will in the near future come to be acknowledged as the type of what such documents *ought to be*, and that, in respect of form and arrangement at any rate, they will furnish models for adoption by medical officers of health throughout the kingdom.

Passing over the ordinary statistics of births, deaths, and marriages in 1898, which we have already noticed in connexion with the Registrar-General's annual summary, we come to an ingenious method which Mr. Shirley Murphy has adopted for the purpose of *demonstrating* the effect *on* the community of fluctuations in mortality. With the help of a life-table published in his report for 1893, and referring to the decade 1881-90, Mr. Shirley Murphy contrasts the London mortality in 1891-98 with that of the previous 10 years. By comparing the mean annual number of deaths occurring since the year of the last census with the annual number that would have occurred according to the rates obtaining between 1881 and 1890, he obtains the number of lives gained or lost in each year, and by the help of certain columns of the life-table he expresses this gain or loss in terms of "life capital," the years of life being obtained by applying the mean future life-time of the life-table to the number of lives gained or lost at each group of ages. "In the county of London there was a mean annual saving of 4161 lives during the period 1891-98, as compared with the decennium 1881-90, and this represents a mean annual salvage of 161,321 years of "life capital." Mr. Shirley Murphy gives a table which shows that, as compared with 1881-90, the mean annual number of lives saved has been steadily increasing since 1891, while the amount of "life capital" in proportion to the number of lives saved has decreased, this decrease being particularly marked in the periods ending with 1896, 1897, and 1898 respectively. This apparent anomaly is explained by the fact that the amount of "life capital" gained is not directly proportional to the number of lives saved, but is dependent also upon the ages at which the life-saving is effected.

---

[1] THE LANCET, Jan. 27th, p 256.

In discussing the behaviour of small-pox in London Mr. Shirley Murphy naturally devotes considerable space to a criticism of the new Vaccination Act. After passing in review the alterations effected by the Act of 1898 in the law with respect to vaccination, he expresses the opinion that at the present time it is too early to form a judgment concerning the merits of the Act or to dogmatise as to whether it will or will not eventually secure the better vaccination of the community. The appointment of a Royal Commission in 1889 led, as might have been expected, to greater laxity in relation to vaccination, and, equally of course, a decision of Parliament in favour of vaccination might have been expected to lead to increase of vaccination subsequent to the presentation of the report of the Royal Commission. The question, however, which needs to be determined and which can only be determined by the experience of subsequent years, is whether the amount of vaccination default will be found in the future to be greater or less than it had been before the appointment of the Royal Commission of 1889. Not till then will it be possible to determine whether the new law with its provisions for domiciliary visitation and for the supply of glycerinated lymph as well as its clauses exempting from compulsion the so-called "conscientious objector" will attain the object in view. In any case, as Mr. Shirley Murphy very properly insists, "the present position of the vaccination law gives opportunity for further legislation such as shall provide an effective system of revaccination of the community. That such a system is necessary for the protection of the people against small-pox is shown conclusively by the experience, not of England only, but that of other European countries also." In connexion with this subject Mr. Shirley Murphy gives a table showing the proportion of children who appear in the London vaccination returns as "not finally accounted for," that is, as presumably unvaccinated. This table reveals the startling fact that in 1896, the most recent year for which returns are as yet available, the proportion of children born in London who at the end of the year had not been *finally accounted for* was equal to more than 26 per cent. The position of London may be imagined in the event of a serious invasion of small-pox when we remember that fully one quarter of the infantile population are, or were quite recently, wholly unprotected by vaccination.

The prevalence of measles is again referred to at some length in the present report, especially in connexion with the question of school attendance. Particulars are given as to the closure of schools in consequence of the prevalence of measles among the scholars in various parts of London, and the opinions of the local medical officers of health are quoted concerning the precautions which should be taken against the spread of this *disease in schools*. Thus the medical officer of health of Stoke Newington expresses his "regret that the regulation of the London School Board requiring that the health officer of the district shall be informed of a child's exclusion from school on account of symptoms of infectious disease is not given effect to as a routine practice, for it would often materially assist the medical officer of health in taking measures to remove further risks of school infection." The medical officer of health of Lambeth, also, who reports that on one occasion during the year as many as one-fourth of the scholars at an infant school were absent on account of measles, is of the same opinion with reference to the School Board regulation above referred to. The question of including measles among the "dangerous infectious diseases" to be notified under the London Public Health Act is now under the consideration of the London County Council, who have invited the opinion of the local sanitary authorities as to the desirability of extending the provisions of that Act to the disease in question. There can be no question as to the advisability, on medical grounds, of providing against the spread of measles amongst the children in our elementary schools, for the disease is not only exceedingly fatal under conditions sometimes obtaining but it frequently leaves behind it mischievous sequelæ which are well known to the profession. Whether, however, the London County Council are prepared to face the very considerable outlay which the notification of measles would involve is another and not unimportant question, and their decision will, we are convinced, be awaited with much interest by the authorities of other large centres of population throughout the country.

SPECIAL FESTIVAL DINNER AT KING'S COLLEGE:

MR. BALFOUR ON SCIENTIFIC TRAINING.

MR. BALFOUR presided on Feb. 14th over a special festival dinner given by the Council of King's College at Lincoln's Inn Hall in aid of the new scientific laboratories of the College. Lord GLENESK, in speaking to the toast of the "Naval and Military Forces of the Empire," elicited loud applause when eulogising the services of the medical officers at the seat of war. Lieutenant-General KENT and Sir JOHN COCKBURN acknowledged the toast.

Mr. BALFOUR in proposing the toast of "King's College" said: The toast, reduced to its narrowest limits, which I have to propose to you is the advancement of scientific research in this great metropolis of ours, in the University which we have recently remodelled, and more especially in that College where I hope and trust your liberality will enable the interests of science to be pursued in the future with an even greater success than they have been pursued in the past. Now, ladies and gentlemen, we have all probably been concerned either in making speeches or in listening to speeches in recent years on the subject of technical education—a very loose phrase, sometimes used or misused to mean education in manipulation or dexterity of hand treatment; sometimes, and I think more properly, used to mean that application of the principles of science to industrial life which we are more and more beginning to recognise as an increasing need of the age in which we live. Now it has been found easy, and I hope it always will be easy, to enlist popular sympathy in anything so obviously useful as the application of scientific method to industrial pursuits. And it will be all the more easy from the fact that we have before us in certain foreign countries striking and admirable instances of the method and of the success which attends or may attend such application of scientific method to industrial pursuits. That everybody can understand. An appeal for that purpose is an appeal which touches the heart of everybody, nearly or remotely connected with the industries on which this nation as a whole lives and on which it must continue to live if it is to live at all. I appeal for something not less necessary, but something perhaps more remote from the ordinary every-day popular educational interest, for I appeal on the present occasion not so much for anything in the nature of technical instruction or applied science as for aid to carry out that instruction in science itself, and those researches in pure science which lie at the base of that instruction, which, from the very nature of the case, can only appeal indirectly and remotely to the great mass of mankind. And yet, after all, science is the essential matter that we have got to consider. Its applications will come and must come—will come almost of themselves, must come in the course of time; but you cannot have applied science without having science in the first instance, and if you do not cultivate scientific research and scientific education it will be in vain that you multiply your technical schools and it will be in vain that you labour to erect a great superstructure where your foundations have been so inadequately laid.

I feel it the more incumbent upon me to urge upon you the claims and the glories of science pursued for itself from the very fact that such science cannot directly appeal to general interest. Among the great number of persons deeply interested in and astonished at, for example, so interesting and sensational a discovery as wireless telegraphy, the majority could neither know of nor take an interest in the speculations of Maxwell or the experiments of Hertz, without which no such discovery as wireless telegraphy would have been possible. These discoverers had indeed fame and reputation among scientific men, but have not even now that world-wide reputation, that currency in the mouths of men, which fall to lesser inventors who have built their work—and rightly and properly built their work—upon the foundations laid by others. Now, according to my view, it is the bounden duty of every great place of university education not merely to keep before it the immediately practical needs of technical or other education, but also not to permit the ideal of scientific investigation to be for one moment clouded. That great object must require, and must increasingly in my judgment require, the generous and liberal coöperation of all classes in the community, whether they be immediately interested in science, intimately acquainted with scientific details, or whether they be merely part of the general public. Men of science themselves are not always in a position to give that pecuniary aid necessary to build the modern laboratory and to equip it with modern appliances, and they are right to call upon all those who take any interest in their subjects to aid them with that pecuniary assistance which in many other counties is extended to them by the Government, but which in this country, rightly or wrongly, by an almost immemorial tradition it has been left chiefly to the energy of private enterprise to provide.

King's College will without question be one of the great teaching centres of the new London University. It requires at this moment, to enable it to carry out that great function, the assistance of the public to supply it with adequate scientific accommodation, especially, I am informed, in the matter of bacteriological and physiological laboratories and lecture-rooms. And it may be some consolation to those who take little interest in scientific investigation unless they can immediately perceive its practical application, to reflect that both bacteriology and physiology have a most immediate and direct bearing upon the health and the happiness of mankind. In both branches of study King's College has proved itself rich in teachers of eminence. I am not going to discuss—it would be almost impertinent for me to even touch upon—the stupendous interests which are bound up in the successful prosecution of those two branches of scientific research, but I may, perhaps, remind you of the enormous practical importance to us, of all people in the world, of some of these more recent researches in bacteriology. Bacteria are a very humble class of organisms, very unjustly abused, as far as I can discover, by ordinary public opinion—they suffer, as other classes have suffered, by having among them a certain number of black sheep; but for the most part they are not only innocent but most useful allies—most useful allies of industry and almost necessary coöperators in some of those functions which have to be discharged if the health of great cities is to be maintained. Our chief interest in them lies with the pathogenic members of the group and we, of all people in the world, are especially interested in dealing with those forms of tropical disease which they produce, for we, of all people in the world, are most interested in maintaining a large number of our population in countries where those diseases born of bacteria are the greatest of scourges. And it is, I believe, to a distinguished professor in King's College, more perhaps than to any other man in this country, that some of the most useful researches in this department are due. I do not know that it is necessary for me at greater length to impress upon you the theme which has been committed to my charge, but I confess that I cannot conclude without admitting that I think this great city has been somewhat remiss in the support which it has hitherto given to scientific investigations in the commercial metropolis of the world. Technical education, if I may revert to that subject for an instant, has in it almost necessarily some element of competition. You hear it said: Germany is doing this, France is doing that, some other country is doing the other; unless you keep abreast of them in your methods of education you will fall behind them in your industrial enterprise. That is a very proper argument, it is a very patriotic argument, it is an argument which I myself have used before, and it is an argument which I shall think myself justified in using again. But I am appealing to you on behalf of the cause which has in it none of this element, this inferior and lower element of competition, whatsoever. Every scientific discovery wheresoever made, be it in Berlin, Paris, London, New York, Vienna, wherever it be made, as soon as it is made it is the common property of every man of science. Nations may erect against each other some barrier of tariff, they may engage in some absurd rivalry animated by I know not what spirit of suicidal jealousy, but men of science wherever they live, to whatever nation they belong, have a cause which is common to humanity at large, which knows no provincial boundaries and which is not interfered with by any sectional rivalry. To that great common fund of knowledge, the basis, after all, of your civilisation as it is—the basis, after all, of the industrial progress you hope to make—I think London should contribute its full share. London takes the tribute, a well-earned tribute, from every discovery made throughout the world, from every advance of civilisation, from every encroachment of civilisation upon barbarism, and from all these London, or some section of it, gets the benefit. Let us, then, who are dwellers in London, feel that we have some obligation to the world at large corresponding to the great position, the international position, which we occupy. Let us do what we can as a community to further that investigation into the *secrets of nature*, that *storming* of the citadels of natural knowledge in which all civilised men are, and ought to be, coöperators. Let it not be said that while there are great centres of scientific teaching in every other great metropolis, we have allowed ourselves for one moment to fall behind in the race in which we, of all people, ought to be leading. It is as contributors to that great end that I ask you for assistance to-night. It is because we know that in King's College we have an organisation ready made to our hand, which has shown us what it can do in the way of scientific investigation and has given us, therefore, an earnest of what it can do in the future in the same great cause; but if it is to do all that it is capable of it demands your assistance, and the assistance of others like-minded to you. It is only by that help, liberally offered, that this great metropolis can fulfil the duty it owes to the scientific bodies in its midst. I ask you now to drink with me the toast of the evening, "Prosperity and success to the future scientific investigations of King's College."

The toast was responded to by the Hon. W. F. D. Smith (treasurer of King's College) and the Rev. Dr. Robertson.

"Science" was proposed by Mr. Justice Byrne. This was replied to by Sir Michael Foster, M.P., who said that with regard to the toast itself, he did not know whether it was gracious or ungracious to say it, but it seemed to him wholly unnecessary, for science had been toasted the whole of that evening. The speech of Mr. Balfour was one continual toast of science, which he ventured to say would carry gladness into the heart of every man of science in this country. Some of his scientific friends abroad had said to him that science did not hold the position in this country that it did in theirs, but from that evening he could appeal to the speech of their chairman. Science had several aspects: there was the science militant, which tilted against every opinion and tradition, and there was the extreme wing of this science militant, which might be called the science blatant. Science blatant was always making pretensions for science to which science itself made no claim. The science blatant was preached by men who had never taken part in the fight or in the work but had stolen the trumpet from someone and simply blown it. Then there was the science vigilant, and vigilant was, he considered, the real adjective for the science which was always wide awake, which was always looking out for occasions for advance, and which was always looking carefully on its own defects and striving to profit by them. Lastly, there was the science mendicant. "Leech" was in old time the term for a man of learning, and it held good still, for scientific men were always crying "Give, give." And why was that? Because they were never content with what they had, because everything they had was always depreciating in value and use. It was because old appliances had to be thrown away and new apparatus procured that they were continually demanding help

The Bishop of LONDON proposed the health of the Chairman, who briefly replied

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD

On an Outbreak of "Fever" in the Village of South Witham,[1] by Dr R BRUCE LOW —South Witham is a small village in South Lincolnshire in which the prevalence of an anomalous "fever" was brought to notice in a somewhat unusual way In the course of the four weeks ending on Dec 6th, 1898 four deaths occurred in a farmer's family in the village under circumstances which led first to local suspicions of criminal poisoning and later to representations to the Home Secretary with a view to the exhumation of the bodies Meanwhile, however, the occurrence of subsequent cases of "fever" in the village became known and the matter was referred to the Local Government Board by the Home Office for the determination of the nature of the prevalent malady Dr Stell, who had attended the cases of illness in the farmer's family, had formed the opinion that all the cases were in fact enteric fever of unusual type This conclusion Dr Bruce Low, after careful inquiry into all the circumstances, considers as the most probable solution. If the farmer's family alone had been in question it would have been impossible, from the clinical history available, to accept or to reject a diagnosis of enteric fever The symptoms had been those of an acute and rapidly fatal enteritis, complicated by meningeal symptoms The latter had, indeed, been so marked as to suggest that the patients had suffered from cerebro spinal meningitis and not from enteric fever at all But a series of cases followed in the village, the majority of which were evidently quite typical enteric fever Between the date of attack of these typical cases and the original illness in the farmer's family intermediate cases occurred which, though presenting the usual symptoms of enteric fever were also attended by unusual meningeal symptoms such as had been manifest in the farmer's family Dr Bruce Low also ascertained that every household invaded by the illness had come into some relation with the farmer's household of a kind which would permit explanation of enteric fever having been introduced from that source The value of Dr Bruce Low's observations would have been enhanced if it had been possible to obtain post mortem examinations or if the serum test had been employed But the numerous clinical data which he gives are well worth noting for comparison with those in other cases where similar doubt and difficulty arise

We have recently received four other reports of inspectors of the Medical Department of the Local Government Board to which, as their interest is in the main local and administrative, we can only make brief reference In *Reports as regards the Eton Rural District* Dr Ralph W Johnstone deals with a number of local insanitary circumstances, particularly in relation to recent diphtheria prevalence The obstacles to sanitary progress in this and in similar low lying districts bordering the Thames are considerable, but evidently many of them could be overcome if the place had a local authority of greater vigour and determination than the Eton Rural District Council Dwellings in most of the villages have their own leaky cesspools in proximity to and polluting the water of their shallow wells This is unsatisfactory enough, but in the growing parts of the district for instance on the borders of Slough and Eton the condition of new dwellings is in some ways worse They obtain water from the public water service but they have no sewers, and instead have more or less water tight cesspools of comparatively small capacity built in accordance with local by laws Such cesspools obviously require frequent and systematic attention to prevent overflowing But in this district the whole onus of cleansing cesspools is placed upon the occupier instead of being effected, as it should be, by the local authority. As a result, in the semi urban localities in question, overflowing of cesspools and "backing up" of house-drains is extremely common and gives rise to most unwholesome pollution of the soil about and beneath the dwellings In this district the undesirable custom of allowing houses to be built below the natural ground level on sites which have been excavated for brick earth appears to be common In a second report Dr. Johnstone deals with complaints from persons in the district living near the Grand Junction Canal of the nuisance arising from the use of the land bordering that canal for the deposit of London house refuse which is transported thither by the contractor to the Kensington Vestry From the view-point of sentiment, in any case, these complaints have a substantial basis, though Dr Johnstone is unable to substantiate a further allegation that these nuisances have been responsible for recent diphtheria prevalence in their neighbourhood

Reports such as that by Dr. G S Buchanan and Mr R H Bicknell—*Upon Inspection of the Gathering Grounds and Waterworks of the Bolton Corporation*—might be multiplied with advantage to the progress of public health measures in the country. The inspectors report a large number of potentially dangerous conditions affecting the gathering grounds and the reservoirs of the Bolton supply, and they are unable to regard the filtration practised as sufficient uniformly to remove the risks to which these conditions give rise When it is remembered that Bolton supplies not only its own borough, but seven other urban districts and some rural areas—in all over a quarter of a million of population—the importance of placing the supply above suspicion is obvious In view of the large powers which it has obtained from Parliament, and of the profit (about £14,000 yearly) which it derives from the water undertaking, the Bolton Corporation should find no difficulty in at once doing away with the sources of pollution described in this report It is surprising to read that in matters so closely affecting public health as the water supply this corporation appear to have hitherto excluded their own medical officer of health from their councils In this and other ways they seem to have failed to give the water consumers many of the advantages which municipal control of a water service is intended to confer, and instead to have regarded their water business too much from the view point of a third rate water company

Dr F. St George Mivart has recently contributed two reports upon local inspection of rural areas—*Upon the General Sanitary Circumstances and Administration of the Chailey Rural District* and the *Sanitary Circumstances of Biggleswade Rural District* respectively

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 7115 births and 5032 deaths were registered during the week ending Feb 10th The annual rate of mortality in these towns, which had declined from 30 9 to 21 2 per 1000 in the five preceding weeks, rose again last week to 22 8 In London the rate was 20 4 per 1000, while it averaged 24 4 in the 32 provincial towns The lowest death rates in these towns were 12 6 in Croydon, 14 4 in West Ham, 15 8 in Swansea, and 16 5 in Nottingham, the highest rates were 32 3 in Blackburn, 34 2 in Salford, 34 3 in Wolverhampton, and 35 1 in Preston The 5032 deaths in these towns included 449 which were referred to the principal zymotic diseases, against numbers decreasing from 578 to 427 in the seven preceding weeks; of these 138 resulted from whooping cough, 115 from diphtheria, 82 from measles, 39 from diarrhœa, 37 from scarlet fever, 34 from "fever" (principally enteric) and four from small pox. No fatal case of any of these diseases occurred last week either in Derby or in Birkenhead; in the other towns they caused the lowest death rates in Nottingham, Bradford, and Hull, and the highest rates in Wolverhampton, Liverpool, Salford, and Preston The greatest mortality from measles occurred in Plymouth, Wolverhampton, Leicester, and Halifax; from scarlet fever in Oldham and Sunderland, and from whooping cough in Croydon Liverpool, Salford, and Newcastle The mortality from "fever" showed no marked excess in any of the large towns The 115 deaths from diphtheria included 51 in London, 12 in Sheffield, 11 in Leeds, eight in Leicester, and five in Liverpool. Three fatal cases of small-pox were registered last week in Hull and one in Leeds, but not one in any other of the 33 towns. There were 17 small-pox patients under treatment in the Metropolitan Asylums Hospitals at the end of the week, against 24 and 21 at the end of the two preceding weeks; one new case was admitted during the week, against five, four, and none in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Feb. 10th, was 2089, against numbers decreasing from 3578 to 2179 on the 12 preceding Saturdays; 157 new cases were admitted during the week, against 207, 190, and 174 in the three preceding weeks. Influenza was certified as the primary cause of 63 deaths in London. The deaths referred to diseases of the respiratory organs in London, which had declined from 1221 to 432 in the five preceding weeks, further decreased last week to 423, and were 53 below the corrected average. The causes of 69, or 1 4 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Leeds, Hull, Newcastle, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Liverpool, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased from 23·0 to 23 7 per 1000 in the four preceding weeks, further rose to 27·1 during the week ending Feb. 10th, and was 4 3 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 15 9 in Leith and 22 6 in Aberdeen to 31·3 in Dundee and 57·3 in Perth. The 836 deaths in these towns included 19 which were referred to measles, 18 to diarrhœa, 14 to whooping-cough, seven to "fever," three to scarlet fever, and not one either to small-pox or diphtheria. In all 61 deaths resulted from these principal zymotic diseases, against 81 and 66 in the two preceding weeks. These 61 deaths were equal to an annual rate of 2 0 per 1000, which corresponded with the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had declined from 32 to 25 in the three preceding weeks, further decreased last week to 19, of which 15 occurred in Glasgow and three in Paisley. The deaths from diarrhœa, which had been 23 and eight in the two preceding weeks, rose again to 18 last week, and included six in Glasgow and six in Dundee. The fatal cases of whooping-cough, which had been eight in each of the three preceding weeks, increased last week to 14, of which six were registered in Glasgow, four in Perth, and two in Aberdeen. The deaths referred to different forms of "fever," which had been three and five in the two preceding weeks, further rose to seven last week, and included four in Glasgow and two in Edinburgh. The three fatal cases of scarlet fever showed a decline of eight from the number in the preceding week, and were all registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 172 and 212 in the two preceding weeks, further rose to 241 last week, but were 105 below the number in the corresponding period of last year. The causes of 27, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined from 50 3 to 35·5 per 1000 in the five preceding weeks, further fell to 29 7 during the week ending Feb. 10th. During the past four weeks the death-rate in the city has averaged 37 0 per 1000, the rate during the same period being 22 3 in London and 24·8 in Edinburgh. The 199 deaths registered in Dublin during the week under notice were 39 below the number in the preceding week, and included 17 which were referred to the principal zymotic diseases, against 10 and 12 in the two preceding weeks; of these five resulted from diphtheria, five from whooping-cough, three from measles, two from scarlet fever, two from diarrhœa, and not one either from small-pox or from "fever." These 17 deaths were equal to an annual rate of 2 5 per 1000, the zymotic death-rate during the same period being 1 8 in London and 0 9 in Edinburgh. The deaths referred to diphtheria, which had been three, one, and two in the three preceding weeks, further rose to five last week. The fatal cases of whooping cough, which had been three and none in the two preceding weeks, rose again last week to five. The deaths from measles, which had declined from 18 to four in the four preceding weeks, further decreased to three last week. The two fatal cases of scarlet fever showed a slight excess over the average of recent weeks. The 199 deaths in Dublin last week included 30 of infants under one year of age and 66 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a decline from the number in the preceding week. Four inquest cases and three deaths from violence were registered, and 56, or more than a quarter, of the deaths occurred in public institutions. The causes of 14, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE

Fleet Surgeons G. J. Irvine and H. T. Cox to be Deputy Inspector-Generals of Hospitals and Fleets.

The following appointments are notified:—Fleet Surgeon A. J. J. Johnston to the *Edgar* for medical charge on voyage to England and afterwards to Plymouth Hospital. Staff Surgeons: A. F. Harper to the *Edgar* for medical charge on voyage to China and afterwards to the *Victorious*; and J. H. Whelan to the *Thunderer*. Surgeons: P. H. Bannister to the *Benbow*; R. S. Osborne to the *Tamar*, additional, and to the *Robin*, on commissioning, to take passage in the *Edgar*, and for duty, if required. A. G. Eastment, lent to the *Rodney*; and F R. Mann to the *Britannia* for the *Racer*. Surgeon J. E. Powell to the *Centurion*

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel W. Johnston, A.M.S., is appointed Assistant Director at headquarters.

Captain Henry Arthur Berryman, from half-pay, to be Captain, with precedence next below K. M. Cameron, vice A. L. Borradaile, promoted.

Lieutenant-Colonel R. T. Beamish proceeds to Woolwich for medical charge of No. 8 General Hospital; Major H. Carr is posted to the Station Hospital, Shorncliffe, for duty. Major J. S. Edye and Lieutenant E. McDonnell, and Surgeon-Captains H. E. Mortis and J E. O'Connor, Militia M.S.C., joins No. 8 General Hospital for duty. Major A. Wright joins at Woolwich Major E. C. Freeman has arrived at Portsmouth, and Major H. B. Mathias, D S O, has arrived in the Home District.

IMPERIAL YEOMANRY.

C. B. Howse to be Medical Officer.

YEOMANRY CAVALRY.

Surgeon-Lieutenant-Colonel W. J. Naismith, Ayrshire (Earl of Carrick's Own), has been seconded for service with the Imperial Yeomanry.

ARMY MEDICAL RESERVE OF OFFICERS.

To be Surgeon-Lieutenant-Colonel: Surgeon-Major J. H. Hay and Surgeon-Major T. Fort.

MILITIA MEDICAL STAFF CORPS

Surgeon-Major W. W. Lake to be Surgeon-Lieutenant-Colonel.

VOLUNTEER CORPS.

Artillery: 2nd Middlesex: Surgeon Captain A. Thorne to be borne as supernumerary in his corps while serving in the City of London Imperial Volunteers. *Rifle:* 2nd Volunteer Battalion the Northumberland Fusiliers: John Clay to be Surgeon-Lieutenant. 5th (Deeside Highland) Volunteer Battalion the Gordon Highlanders: Surgeon-Captain J. H. Anderson to be Surgeon-Major. 1st Volunteer Battalion the Worcestershire Regiment: James Howard Wilkinson to be Surgeon-Lieutenant. 2nd (Berwickshire) Volunteer Battalion the King's Own Scottish Borderers: Surgeon-Lieutenant D. R. Dobie to be Surgeon-Captain. The following officers will be borne as supernumeraries in their corps while serving in the City of London Imperial Volunteers: 16th Middlesex (London Irish): Surgeon-Captain E. W. St. V. Ryan. 20th Middlesex (Artists): Surgeon-Captain R R. Sleman.

The Royal Army Medical Corps and the Indian Medical Service

The following is a list of successful candidates for commissions in the Royal Army Medical Corps at the recent examination in London

Order of Merit	Names	Marks.
1	T Biggam	2554
2	H Richardson	2532
3	C H Carr	2430
4	W L Baker	2402
5	T W Cotton	2370
6	L Bennett	2275
7	F M Larry	2243
8	D R Dimits	2221
9	J S Twigg	2135

Order of Merit	Names	Marks
10	W J P A lye Curran	2195
11	J Powell	2156
12	R L Argles	2099
13	J G Foster	1971
14	F P Lauder	1970
15	E G Ford	1803
16	F S Walker	1802
17	L M Purser	1800

The following is a list of the candidates for Her Majesty's Indian Medical Service who were successful at the competitive examination held in London on Feb 2nd and following days —

	Marks
J D Graham	3640
C A Sprawson	2936
W H Cazely	2928
W V Coppinger	2812
F A Browne	2785
A Spitteler	2768
M MacKelvie	2651
L J M Deas	2621
W G Hamilton	2620

	Marks
J O S Oxley	2615
H R Mackie	2570
W Lapsley	2521
W D A Keys	2497
A Chalmers	2459
J Good	2453
W McM Houston	2402
G J G Young	2363
S B Godkin	2262

Volunteer Officers' Decoration

The Queen has conferred the Volunteer Officers Decoration upon the undermentioned officers —*North Eastern District Artillery*: 1st Lincolnshire Volunteer (Western Division, Royal Garrison Artillery) Surgeon Lieutenant Colonel Edward Bass Peckitt *North Western District: Rifle* 1st Volunteer Battalion the Royal Warwickshire Regiment Surgeon Major Edward Luke Freer *Scottish District Rifle* 7th Volunteer Battalion the Royal Scots (Lothian Regiment) Surgeon Lieutenant-Colonel James Bruce Ronaldson 2nd (Berwickshire) Volunteer Battalion the King's Own Scottish Borderers Surgeon Major Robert Shirra Gibb *Southern District Rifle* 2nd Volunteer Battalion the Hampshire Regiment Surgeon Major Richard Thompson Cæsar *Western District Artillery* 1st Gloucestershire Volunteer Artillery Surgeon Major John Shaw Carleton

A good service pension of £100 a year has been granted to Surgeon General William Taylor, C B, A M S, P M O on the Staff of the Commander in Chief in India

Transvaal War Notes

Major A S Rose, R A M C, was wounded in the action Potgieter's Drift

In view of the recent Army Order officially sanctioning the services of officers and men of volunteer medical staff corps and bearer companies of volunteer infantry brigades for South Africa steps have been taken to at once raise two bearer companies from the brigades of the Home district

On the outbreak of the war the committee of Queen Charlotte's Lying in Hospital undertook to receive into the hospital for their confinements the wives of soldiers and sailors on active service in South Africa Orders of admission have been issued to 37 women and 15 others are being attended as out patients

The citizens of Edinburgh have resolved to raise a fund by public subscription of not less than £12 000 for providing a Scottish hospital for South Africa The doctors and nurses will all be Scottish, but the use of the hospital will not be confined to the treatment of Scottish soldiers only More than £6000 have already been received

The American Field Hospital the gift of Mr Van Alen and consisting of 25 beds, left the Albert Docks on Thursday, Feb 8th Captain E T Powell R A M C is in charge of the hospital and the orderlies have been furnished by the St John Ambulance Brigade Mr S Osborn, F R C S Eng, chief surgeon to the Metropolitan Corps of the St. John Ambulance Association, who has been attached to this hospital left for South Africa in the *Norman* on Feb 10th

A telegram from Modder river states that an Army Order has been issued improving the status of civilian medical men

A telegram from Lady Randolph Churchill at Durban states that on the hospital ship *Maine* there are now 140 patients, among them being stretcher bearers and men of the Royal Army Medical Corps There are 16 cases of dysentery, 14 of rheumatism three of enteric fever, and four of ague

Messrs W C Windover Turrill, and Sons of Long Acre and South Audley street have ready for shipment to South Africa two "Manders's Flying Hospital Cars" and two "Manders's Flying Ambulance Cars" for service with the Imperial Yeomanry The first named cars are somewhat similar to the Irish jaunting cars and the wounded are prevented from falling from the seats of the cars by straps Between the two seats, on each of which there is accommodation for four men, the dressings, water &c, are placed, and there is also a seat for the surgeon The flying ambulance cars are each fitted with six stretchers — All the cars are fitted with springs specially constructed for travelling over rough roads.

Dr L J Weatherbe, police surgeon of the borough of Sheffield, has volunteered for service in South Africa with the Imperial Yeomanry and has been accepted by the War Office

The St John Ambulance Association, which is entrusted by the Central British Red Cross Committee with the reception and forwarding of material for the sick and wounded to the seat of war, has already despatched 5855 pyjamas, 9293 shirts, 23 603 handkerchiefs, 2319 pillows, 7330 pillow slips, 6409 pairs of socks and stockings, 6210 slippers and shoes 1471 knitted caps nightcaps, &c, 246 pairs of gloves and mittens, 1080 jackets woollen waistcoats, and cardigans, 4735 mufflers, 1021 nightingales and hospital capes, 694 cushions, and many thousands of other articles

The *Times* publishes a letter from Mr Anthony A Bowlby to the Duke of Portland, dated "Portland Hospital, Rondebosch, Jan 15th" in which he says "The arrangements made by the Royal Army Medical Corps for the treatment of the wounded on the field and for their transference to the base hospitals are altogether admirable, and it is certain that in no previous war undertaken by any country have such facilities been afforded for the prompt succour of those injured or for their suitable and safe conveyance by properly equipped trains Many men have arrived at the hospitals in the neighbourhood of Cape Town within 48 hours of being wounded some 600 miles away, and it must be remembered that within this time they have been dressed on the battlefield, conveyed in ambulances to field hospitals, and subsequently removed to the trains It is in consequence of these arrangements that the wounded are all treated at general hospitals placed in the most convenient and healthy situations, where the work of the Royal Army Medical Corps can be supplemented by the experience of civilian surgeons, and it is here consequently that the Portland Hospital is at present of more use than it could be elsewhere The excellence of the general arrangements in this war for the treatment of the wounded cannot be too widely known" A letter from Lord Roberts to the Duke of Portland says "It will I am sure please the duchess and you to know that the Portland Hospital is all that could be desired I have never seen a nicer, better managed, or more comfortable hospital"

The Public and the War

One of the most striking features of the present war has been the remarkable manifestation of enthusiastic patriotism displayed on all sides There is no end to the generous efforts that are being made to help our soldiers in the field and to take care of those who have been left behind What is wanted now is to see that the philanthropic work is properly turned to account by effective organisation The distribution of all the stores of clothing, food, medical comforts and appliances, and tobacco that have already reached the Cape must be a source of some embarrassment and difficulty to the authorities there As regards the hospitals and hospital ships that have been provided by charitable organisations and munificent individuals much money and care have been expended in fitting them out and some of them are already doing excellent service They have accommodated quite a number of wounded officers and men and all who have gone round the institutions, the Portland Hospital for example and inspected the arrangements have expressed their satisfaction, and, what is more to the point, the patients themselves are gratified with the treatment they are receiving

Major Marchand's Medical Officer

The name of Dr Emily, who was recently promoted out of his turn to the rank of medical officer of the first class, has now been officially inscribed on the officers roll of the Legion of Honour as an additional reward for his "exceptional services" Dr Emily possesses an excellent record for professional efficiency and zeal and has contributed several papers of merit to medical journals His method of treating guinea-worm by the injection of corrosive sublimate solution, if possible, into the body of the parasite, but, failing this, into the tissues adjoining it, would seem to deserve a trial.

"Audi alteram partem."

"THE PREVENTION OF SYPHILIS BY TREATMENT."

To the Editors of THE LANCET.

SIRS,—With reference to the letter in THE LANCET of Feb. 3rd (p 341), from Dr. C. R. Drysdale under the above heading, while probably many will agree with him that "syphilis being a contagious disease ought if possible to be prevented" by some "legal plan," some on the other hand may not estimate at a high value the means which he mentions to that end—"notification and prosecution of persons who voluntarily infect their neighbours." Notification implies the possibility of recognition of the existence of disease, and as one objection raised against the value of compulsory examination was based on this asserted difficulty the two methods are on this point, assuming the existence of the difficulty, on the same footing. Besides, the value of notification towards prevention lies in the extent and degree to which it would bring the disease under treatment; in range it is limited to those coming within the professional purview of the notifier, it can have no action on that large
umber who while diffusing the disease abstain from all
pplication for treatment until physically compelled to seek
elief; and to be valuable for prevention it must be asso-
iated with efficient continuous treatment so long as the
isease remains capable of transfer by contagion and with
mpulsory withdrawal of the sufferer from all ways of its
ssemination. Hence from a sanitary point of view the value of notification over the compulsory examination and enforced detention of the old Acts is not apparent; rather it is less in that so far as prevention is concerned it starts from pronounced disease compelling the sufferer to seek treatment, while the compulsory examination anticipated this period and withdrew the infecting person from acting as a focus of infection long before that condition had been arrived at, though to be efficient its mode of action follows the old compulsory lines. Nor is it apparent how notification could "give us correct information as to the extent of the evil" in view of its necessarily limited range of action, and before it can be acted upon the notifier must be relieved from the present legal disabilities attendant upon it.

Again, with respect to the "prosecution of persons who voluntarily infect their neighbours" the difficulties attending the procedure are many. We know already how profoundly obnoxious was the assumption of the rôle of the informer when directed only towards the recognition of the existence of disease and how much greater would be the obstacles when the additional object of punishment was entailed. I venture to think that these suggested means of prevention are, from a sanitary point, no advance over the old extinct procedures.

In his last paragraph Dr. Drysdale, referring to the last meeting of the British Medical Association, mentions an apparent wish on the part of some "to introduce the Parisian system into London," concerning which system he makes extracts from a pamphlet sent him recently by Professor Fournier. Although present and taking part at this signally inconclusive and abortive meeting and hearing a variety of opinions I cannot recall to mind any prominence given to the system bearing this designation. Speaking personally, my advocacy was for the prevention of syphilis by curtailment and control of its main diffusing medium—prostitution—and by sanitary legal action against its transfer. And, indeed, by the extracts given from Dr. Fournier's pamphlet we find that even in Paris the prevention of syphilis through "repression of prostitution by administrators and police measures" was not without "benefits," though the measures were "insufficient for their purpose" and failed "because so disgracefully unjust in application"—features of a remediable character and having reference not to the principle but to the means adopted. And that failure is no necessary sequel is shown by the results arrived at in the German army and in our own, and by the experience of the Ionian Islands and of Malta
Sir H. Storks and Mr. Inglott, to mention no
import.

The great extent to which the disease preval
pointed out by Dr. Fournier, and the evidence
effect among us is indicated in the addresses t
Minister in June last; the formulation of a pla

"THE PHYSIQUE OF THE BOERS."

To the Editors of THE LANCET.

SIRS,—In the interesting article on the physique o
Boers in THE LANCET of Feb. 10th (p. 410) a
ment occurs which I think will cause some su
to those of your readers who have lived in Holl
The writer says: "In so far as they are of D
descent the Boers should be small. The French bl
which is mingled with that of the Dutch would
tend very considerably to increase the height of the B
The French, though taller than the Dutch, are not so tall
the English." I believe that the notion that a Hollander i
short squat man is derived from the days when almost o
only intercourse with him was in his sailor capacity, sailo
being generally men of short, thick-set build. We a
also familiar with his outward man through the seventeenth
century painters of rural life whose rustics are generally
clad in garments that give them a "broad-in-the-beam"
aspect. What struck me in the Dutch physique—I lived
several years in Holland—was that it was by no means of the
Teniers type and that gaunt tall men were quite as common
as with us English. The Dutch are certainly of a greater
average height than the French; but the stature of both
varies somewhat in the different provinces of the two
countries. The mingling of the French with the Dutch
blood would, I venture to say, tend to diminish rather than
to increase the height of the Boer; but it is doubtful
whether the influence of the French upon the Boer physique
is not *une quantité négligeable*.

I am, Sirs, yours faithfully,

HENRY ATTWELL.

To the Editors of THE LANCET.

SIRS,—Your correspondent who wrote last week (p. 401) on the subject of the physique of the Boers scarcely does justice to the physique of the Briton. He takes as his standard of comparison a crowded street in Glasgow, factory women in a Lancashire town, the inhabitants of a West-end slum, and ditto East-end, thus comparing a healthy agricultural class with the unhealthiest classes in the United Kingdom, if we except the healthy open-air workers in Glasgow. If he cares to revise his opinion let him go to any agricultural show in the country or even to the cattle show at Islington, and he will see a class more than able to hold its own in comparison. As it is not the time of year for these shows the next best opportunity is at a meet of the hounds or a local country steeple-chase. Then apart from the distinctly agricultural class take the athletes from the football and cricket fields and other branches of athletics. He seems needlessly troubled about replacing the Highland Brigade; it would be very interesting to know how many of them are pure crofters and how many town-bred; I fancy your correspondent would be astonished at the figures.

I am, Sirs, yours faithfully,

Forest-gate, E., Feb. 12th, 1900.

E. T. A. BOYTON.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—Dr. Edmunds has still failed to grasp the meaning of my query, "If the patient does not absorb a in each case why do we get a similar result?" er's mask or a Krohne inhaler) By "we" I munds and myself and by "similar result" I anæsthesia with regular pulse and respiration ntracted pupils A list of deaths under anæs- e of them given from a Krohne inhaler) is no is query, to which I am still waiting a reply.

unds's questions are · 1 "Can he show any measured dosage other than the volumetric ion of air charged with the vapour of the anæs- My answer is that by "dosage" I mean the sorbed by the patient, not the amount presented d excluding the use of a closed inhaler, which is too , I know of no method of estimating accurately it of chloroform absorbed except by watching its the pulse, respiration, and pupils 2 "Can he any apparatus by which precise and registrable n be secured other than by the improved Krohne "

ply is that neither the Krohne inhaler nor any achine that I have met with ensures the patient's g a "precise and registrable" amount of chloroform

A large portion of Dr Edmunds's letter is devoted ing that while the Krohne inhaler can supply the with chloroform it cannot be expected to provide ninistrator with brains I quite agree As in surgery , the rule holds good that multiplicity of instruments ever compensate for lack of knowledge A further of the relative (not absolute) safety of the open method ministration is found in Dr Edmunds's concluding re- s He says "*For some 40 years I was in the habit of g chloroform off a towel or anything else. I have never any sort of anxiety about my chloroform in any single*" (The italics are mine) Comment is needless

I am, Sirs, yours faithfully,
C HAMILTON WHITEFORD

ymouth, Feb 12th, 1900.

IE ELECTION OF A PARLIAMENTARY REPRESENTATIVE FOR THE UNIVERSITY OF LONDON.

To the Editors of THE LANCET.

SIRS—The result of the election for a Member of Parlia nent for the University of London should be a source of ery legitimate pride to the graduates The comments, however, which have appeared in the daily papers appear to show that the writers of the articles have not a very clear grasp of the facts which have influenced the electors. Although I cannot profess to have studied these articles with any great care the general impression which they have left on my mind is that the Conservative papers imagine that a great success has been won for the Tory party, and, on the other hand, that the papers which support the Opposition imagine that their party has been badly treated by a number of persons amongst whom they expected to find a majority of militant Radicals The writers of the political articles in the daily papers cannot perhaps be expected to look at such a position as prevailed in this election from a broad standpoint, nor can they be expected to have any knowledge of the various side issues which in a constituency like that of the University of London necessarily affect a considerable number of votes As a matter of fact it seems to me that the election did not turn on political matters Possibly a majority of the intelligent people in most constituencies consider that the present Government has obviously neglected its duties but the same majority probably think no less strongly that members of the front Opposition bench if they were in power would prove no more capable And it is my opinion that until a new party with a definite policy has been formed by the man who will within a short period be Prime Minister there will be no active agitation against the present Government

The result of the election of a Member of Parliament by e University of London is satisfactory, in the first place, cause beyond doubt the best man has been chosen The ewly elected Member by his training is eminently fitted to nstruct the Members of the House of Commons on matters great importance to the country concerning which most them are either ignorant or careless—careless possibly, because no votes are to be gained by paying attention to the subjects And apart from the positive side of the question it is satisfactory that the University of London has secured as its representative a man whose reputation has been made in municipal provinces Again, it is satisfactory that the London University has avoided electing the gentleman who was so quick in obtaining the support of an electioneering association with which he had for a long time been working It might very easily have happened that the determining cause of the selection should prove some dissatisfaction with the manner in which the affairs of the University have been managed But the many graduates who strongly disapprove and regret the alteration which has been made or is about to be made in the constitution of the University, putting all personal considerations aside, have undoubtedly voted for the man they thought would best represent the University.

The London graduates who in the past have had to work very hard to obtain a degree have felt aggrieved that by an alteration in the constitution of the University it is practically certain to happen that degrees of the same denomination will be obtained on much easier terms There can be no doubt whatever that for a long time there has been considerable and great injustice to the London medical student, and that he has not been able to obtain a medical degree without an enormous amount of work in subjects beyond the ordinary medical curriculum A student who went to Edinburgh or one of the other Scottish universities was, if he were a man of ordinary ability and fair application, practically certain to obtain at the end of his time a medical degree which he would afterwards find of great use to him in his battle with the world If instead of choosing Edinburgh or some other Scottish university the same student had come to London he would not have been able with the same amount of work and in the same time to take a medical degree, because the standard of the University of London required either that he should work harder or that he should spend an extra amount of time over the work. The teachers at the London medical schools, some of whom have been very active in obtaining the alteration in the constitution of the University, have undoubtedly, whether consciously or not, been dominated by the idea that a more easily obtained degree will be accessible under the altered constitution Now, by some of the older medical graduates this has been thought a distinct grievance, and it was quite within the bounds of possibility that they might have shown their discontent with the alterations by voting not for the best man, but for someone entirely opposed to the alterations which are now to take place in the University of London Again, it is conceivable that many members of the University, which has hitherto been free from any theological connexion, are looking forward with dislike to an alteration by which colleges which represent some of the better known forms of heresy become parts of the University; and that there should be thus a department formed for the study of pathological theology

It is a most hopeful portent for the future success of the University that setting aside all extraneous considerations the London graduates have elected a Member who will be able both to enlarge the sphere of usefulness of the University and also to instruct the Members of the House of Commons on subjects on which they are at present in sad need of light and leading

I am, Sirs, yours faithfully,
AN OLD MEDICAL GRADUATE

THE BATTERSEA AND CLAPHAM MEDICAL SERVICE

(FROM OUR SPECIAL COMMISSIONER)

IN October, 1896, a few medical men residing in Battersea and Clapham held a small meeting to discuss the question of medical aid for those who could not afford to pay the ordinary fees Dr R H Barkwell took the initiative in this movement and was elected president of the association which was formed on that occasion At this time most of the contract work done in these neighbourhoods was in the hands of the London and Manchester Industrial Assurance Company, Limited, and the medical men naturally objected to be in the service of an industrial company. They were imbued, on the contrary, with the idea that such insurance against sickness by small weekly payments as might be justified should be organised by those who did the work—namely, the medical attendants themselves. The medical men objected to being used as decoy ducks for an insurance business, and thought that the dignity of the profession was likely to be compromised if they worked for an organisation when they had no voice in the management. At the first meeting there were nine medical men present and seven of them at once undertook to form the nucleus of a medical service to be managed by the medical men themselves. Of course efforts were made to detach the medical officers from the service of the London and Manchester Industrial Assurance Company, but only two among them responded. The others expressed the fear that the company would import medical men to take their places if they sent in their resignations and that there was no organisation sufficiently strong to support them in the struggle that would ensue. Indeed, this fear was subsequently justified, for the company in question has imported two practitioners, thus increasing the competition prevailing. In spite, however, of this danger the small group of medical men who had met together were not long in setting to work. At their first meeting they adopted a set of rules, this task being greatly facilitated and simplified by a neighbouring organisation of the same description—the Wandsworth Medical Aid Society. The rules of this latter body served as a model and basis for the new society now brought into existence and designated the Battersea and Clapham Medical Service.

This society differs from the old provident dispensaries by the facts that the medical officers themselves form the executive committee, that it is absolutely self-supporting, and that no appeals whatsoever are made for charitable donations. There are no honorary subscribers. The members consist solely of persons living in Battersea or Clapham who "are unable to pay for medical advice in the usual manner." All persons desirous of becoming members must make a declaration that they are unable to pay for medical attendance and that they are *not suffering from any kind of illness*, whether acute or chronic. Any inaccuracy in such declarations confers on the committee the right of immediately expelling the member, and all the contributions paid by him are forfeited. The members pay 1*d*. per week. The highest amount charged for any number of children under 12 years of age is 4*d*. per week, and these must all belong to the same family. Further, the members must pay 1*d*. per quarter as a management fee, the maximum sum per family being 4*d*., and 1*d*. is charged for each new card of membership. The payments are made in advance and are marked on these cards. All payments are made to the collectors except in cases of certificates, vaccinations, and confinements, when these have been arranged for apart from the service. Members who are in arrears with their subscriptions for more than one month must pay 1*d* per week fine, and if in arrears for more than 13 weeks their names are erased from the books. If, however, the committee so decide the excluded members may be re-admitted on paying the arrears and fines for one quarter. Of course persons who are actually suffering from illness are not admitted unless especially recommended by one of the medical officers of the service, and then they must pay for one quarter in advance and an entrance fee of 3*s* 6*d*. Members who have contracted a disease through their own fault are not entitled to medical attendance. Married women who are members will receive medical attendance during their confinement on payment of from 10*s*. 6*d* to £1 1*s*. This payment may be effected by weekly instalments if the whole sum is paid in advance Miscarriage or premature birth at any stage, cannot of course, be paid for in advance. The fee for this is 10*s* 6*d* and members are allowed three months to pay the same in weekly instalments, but this does not exempt them from the payment of their ordinary subscriptions. If such payments are not effected in the time prescribed the committee may erase the defaulters from the list of members. The medical officers have the right to refuse to attend members for confinements, but they must attend these patients when a month has elapsed after the confinement The medical officers do not visit domestic servants at their master's house, but servants may obtain advice at the medical attendant's surgery or in their own home if it is situated in the district Messages for attendance must be received before 10 30 A.M., otherwise a fee of 1*s*. 6*d* is charged. For medical certificates a fee is charged of 1*s*. each. The medical officers supply medicines, but the members must provide their own bottles. Such, briefly, are the rules of the society

No sooner was it known that such an organisation was about to be established than several persons applied for the post of collector. One among these was selected and he has been retained in the employment ever since. The first subscribers were enrolled in the second week of November, 1896, so it will be seen that not much time was lost in the work of preliminary organisation; indeed, subscriptions were coming in within a month of the date on which it had been decided to establish the medical service. During the first two months the medical service had 63 members and in 1897 there were some 400 members The receipts from subscriptions and fines amounted for the first seven and a half months to £103. During the last six months of 1898 they rose to £175 and during the last six months of 1899 to £177 Thus there has been a steady progress, but the general expenses are still very heavy as compared with the receipts The relative expense would diminish if the number of members was augmented, as there would be a larger margin of profit. Thus 8*s*. 6*d*. per week is paid for the rent of three rooms. One of these rooms serves as a meeting-place for the committee and as the collector's office. Here [illegible] the registers and books are kept and are open at all times to [illegible] the inspection of the medical officers The collector himself [illegible] receives a regular salary of 9*s*. a week and has the two other [illegible] rooms attached to the office rent free to live in. Then he [illegible] receives a commission of 10 per cent. on all the money [illegible] he collects. But he has to give the whole of his time [illegible] the work. The number of members has now incre[illegible] much as to make it necessary to employ a second co[illegible] he is paid 5*s* a week and 10 per cent commissi[illegible] expected to give only half his time Last quarter [illegible] the receipts or expenses amounted to £23 1[illegible] amount collected was £83 9[illegible] seen, therefore, that the working expenses [illegible] a quarter of the total receipts. Th[illegible] the case when the number of membe[illegible]

Here, as elsewhere, [illegible] establishing an effective check on the colle[illegible] solved. The service is quite and absolutel[illegible] its collectors, but if at any time a dishonest [illegible]llector should be employed it would be difficult to detect [illegible] defalcations. The principal check is for the medical atten[illegible]ant to insist on seeing the patient's card, but if the mem[illegible]ber is not ill there is no pretext for examining the card. Certainly when from the books it appears that a member [illegible] is not paid, independent inquiries might be made at [illegible]mber's house. But who is to make such inquiries? [illegible] to be expected that medical men will undertak[illegible] [illegible]ive work every time a few pence [illegible] hand, there is this security, that [illegible] dishonest, would not run the risk of [illegible] sake of a few pence here and there. [illegible]ficulty is involved in the question of [illegible] respect the insurance companies have [illegible] their collectors do not hesitate to tout. The [illegible] members for the Battersea and Clapham Medical Service depended at first on the medical men themselves who brought in the members of their own private clubs Some of the medical officers had poor patients who instead of paying fees paid small sums weekly direct to their medical advisers. These patients were handed over to the collectors. Then when a medical practitioner found that his patient could not pay the usual fees he suggested that he should enrol himself as a subscriber to the medical service. But the committee is constantly striving to impress on the collectors that they must not tout. A few weeks ago the following resolution was carried unanimously:

> That the secretary be instructed to write to each of the collectors calling their attention to the fact that canvassing for patients in any part of the district is not allowed

The fact that the medical service has now a staff of 16 medical attendants greatly contributes to its popularity, as it gives the members a large choice If in this the advice of the collector is asked by a new member the rule is that he should recommend the medical officer who is nearest at hand. Members have the further advantage that they may change their medical attendant, but not during an illness. To change their medical attendant they must wait till the half-yearly meeting and give notice to their collector a fortnight in advance.

With regard to the possibility of abuse a list of new members is drawn up from time to time and sent round to all the medical officers If any one of them has reason to believe that one of the members can afford to pay the usual fees he need only draw his pen through the name The member is then at once struck off the books, so that it rests in the hands of the medical men themselves to prevent abuse Organised on these lines the service is working very smoothly. Formerly the managing committee or board of the medical staff met every month, but everything is now so well organised that there is little or no work for them to do; consequently, unless some unexpected emergency arises, they now only meet once a quarter Thus far, then, the service has been fairly satisfactory, but the profits are not large. Some 25 to 30 per cent must be deducted from the receipts to cover the cost of the drugs which the medical officers have themselves to provide and we have already seen that the working expenses slightly exceed another 25 per cent It is, therefore, probable that the net profits do not amount to quite 50 per cent of the receipts Consequently there is need of improvement in this respect

To my mind the weak side of this organisation is certainly the limited scope of its action It has taken up one single question and has therefore only received the support of those who are interested in that one question The time has perhaps arrived when an appeal might be made to all the practitioners of the districts in question to join hands and deal with all the problems in which the profession is concerned What is wanted is a general medical union, not merely for the purpose of providing medical aid to those who are too poor to pay the usual medical fees, but to deal with other questions at issue, such as the abuse of hospitals and the competition of the clubs and the insurance companies Such grievances cannot be abated by the work of the 16 medical officers of the medical service They can only be dealt with by a powerful and general union of all the practitioners of the district such as that formed at Cork and recently described in these columns[1] But the medical service now established could serve as a centre and starting point for the formation of a general medical union of the practitioners of the districts of Battersea and Clapham Dr W Carey, 41 Bolingbroke grove, Wandsworth common, S W, is the secretary of the Battersea and Clapham Medical Service Doubtless if he received some encouragement from the practitioners in these districts the organisation that he represents would take the initiative in convoking a meeting so as to form a union of all medical men in the neighbourhood for the purpose of dealing with the ethical and economical problems which affect the general interests of the profession

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT)

The Progress of the Plague Epidemic its Continued Spread to Fresh Areas and its Serious Development in Bombay City —The Jigger Pest

THE plague mortality in India for the week ending Jan 21st shows that the disease is again increasing The record of the week is 1595 deaths against 1279 in the previous week The disease, moreover, is spreading to fresh places We hear for example, from Patna that about 13 villages in the Barh subdivision of the Patna district are badly infected and that some hundreds of cases have occurred, although the official returns only give 52 deaths A case of plague detected in Rangoon has proved fatal the victim being a girl who arrived from Calcutta on Jan 13th The house in which the deceased died has been burnt and a segregation camp has been formed in an isolated position The case appears to have escaped the notice of the Government medical inspecting staff The town of Navsari which is in the Gaekwar territory, and is the headquarters of the Parsee priesthood hitherto free now reports a serious outbreak Again, a case has occurred at Arrah and an outbreak of a serious character is reported from Tripatore in the Salem district, where the whole town is said to be infected I give these details to emphasise the actual state of the plague epidemic which is not always correctly indicated in the official returns Plague has greatly increased during the past week in the Mysore State (253 cases being reported as against 40 last week), in the Hyderabad State (154 cases, against 101), and in Bombay City (official figures being 471, against 379) As I foreshadowed Karachi is threatened with a renewed outbreak. More cases have occurred and evacuation from infected areas has now been adopted. It is satisfactory to hear that inoculation has been received with favour by the Khoja community In Bombay city the general mortality for the week has risen to 2289 As the quinquennial average without plague is about 570 for the week this enormous mortality shows how severely the disease is once more raging Small pox and measles continue, but deaths from these diseases account for a very small part of the increase Week after week the official returns of plague for Bombay city give a small proportion of the actual mortality, and this week 471 deaths only are recorded I must point out that the mortality from plague alone in Bombay city possibly amounts to 1500, for the week in question, as there are no other causes to account for the increase In the city of Calcutta there is not much change A few cases continue to be seen and the plague mortality for the week is estimated at 56 From an examination of the mortality tables for the whole of the year I find that the deaths returned as from plague in Calcutta exceed the excess of the mortality above the average It must be borne in mind, however, that Calcutta has been but little affected by cholera and has been otherwise exceptionally healthy during the year The estimate of plague is therefore probably correct But many observers do not accept the same conclusion regarding suspected cases The causes of death in these cases may be very doubtful, but on the above grounds I should be more disposed to consider that they arose from natural causes and were not due to plague At the present time both the city and suburban districts have a higher mortality than normal In view of the discovery of more living cases of plague, the continued high minimum of estimated plague mortality, and the interval which has now elapsed since the last definite development I regard the outlook as somewhat threatening

The Government of India have published for general information the following memorandum of Dr Becker, principal medical officer to the German Imperial troops in East Africa, on the mode of treatment of the jigger pest —

> The jigger has become an unpleasant trouble to man as the pregnant female bores with its head into the human skin and in consequence of the large quantity of eggs swells to the size of a small pea and in the shape of a white ball This results in a small ulcer the skin not being red in the beginning, but gets inflamed in the course of a few days If the parasite is not removed the inflammation increases and matter forms whereby the parasite is then removed The trouble caused by the jigger at the commencement is of small account The pain of the boring with which it enters the skin is so small that it is usually not noticed Later there is irritation in the affected part With increasing inflammation the irritation gets stronger and can attain the length of pain Festering wounds, if not cleaned as in the case of all neglected wounds, can cause serious inflammation gangrene and even general blood poisoning As the jigger lives on the ground it seeks out the foot as the most suitable part for its purposes—the soles of the feet especially the toes these being parts more protected from rubbing the free ends underneath the nails, the wrinkles of the joints &c. It is rare for it to attack the thighs or scrotum and other parts of the body
>
> The mode of prevention and treatment is easy The wearing of thick boots such as are specially worn by Europeans and soldiers, is a strong protection against jiggers Still better are high boots It is recommended to rub copaiba balsam or Peru balsam into the feet or to powder the stockings with insect powder The principal thing however is to have the feet carefully examined—a matter of vital importance to the bare-footed population As soon as a jigger is noticed in the skin it must be removed with the utmost care With a view towards this the little opening made by the jigger in order to get into the skin must be enlarged so that the periphery of the swollen insect is laid bare and easily scooped out after which the wound should be cleaned out, and it generally closes quickly if kept clean An unsuccessful attempt resulting in the pregnant jigger being lacerated appears to cause severe inflammation which should be treated according to the usual rules of surgery Natives usually attain great dexterity in removing the jigger By carefully attending to the feet the above unfortunate results—ulcerations &c —are uncommon In case of indolence or indifference on the part of natives attempts must be made to convince them In many cases—for example, soldiers—punishment must be meted out to them When soldiers become incapable of marching or performing their duties on account of jiggers it is permitted to punish them as, had they examined their feet daily and removed the jiggers in time there would have been no need for them to absent themselves from duty

Jan 25th

COMPENSATION TO A MEDICAL OFFICER —The Local Government Board has determined that the compensation payable to Dr C W Belfield for loss of office as district medical officer in the Bristol Incorporation [illegible] at the rate of £50 9s 6d per annum

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Medical Charities.

IN a former communication[1] the financial condition of some of the Manchester medical charities was mentioned as given by Mr. F. Brocklehurst in his paper read before the Manchester Statistical Society. In addition to the hospitals the financial condition of the dispensaries as distinguished from the Provident Dispensaries is equally unfortunate. The Hulme Dispensary is working at a loss and the Chorlton Dispensary reports a deficit on the year of £69. Though not quite in the same category the Nurses' Institute cannot extend its operations for want of funds. But the spirits of hospital managers are not easily damped. The report of the Royal Eye Hospital states that the financial position is satisfactory, although, according to Mr. Brocklehurst, in 1898 deficits of £2000 had to be cleared off by realising on investments and last year the expenditure exceeded the income by £286. In this case Mr. Brocklehurst seems to have been inaccurate, for Mr. H. J. Goldschmidt, the honorary secretary, corrects his statement and shows that the deficit of £2000 was owing to an enlargement of the hospital, and that as regards the £286 this deficit and the £2000 were paid out of money received during the year and from cash in hand, and that no investments have been realised to pay for an excess of expenditure over income. It is cheering to see this, and instructive as showing how good one story may be till the other is told. The Eye Hospital does an immense amount of good work, the total number of out- and in-patients being 25,050. But more than half the number come from districts outside Manchester, and this wide area sends more patients than subscriptions. But Mr. Brocklehurst does not deal only with the financial question. According to the reports 217,527 cases of all kinds were treated in 1898, but as many of them were old patients reappearing in the various categories as new cases he thought that 150,000 would be about the number of individuals who had received treatment at the medical institutions in 1898. During the discussion on the paper Dr. J. Niven said that if the estimate were correct it revealed either exceptional poverty or that thousands were using the charities who were able to pay. Dr. D. J. Leech spoke strongly as to the misleading character of the reports issued by the charities, which were compiled to attract subscribers. He referred to the report of the Infirmary and said that the same person when transferred from the "in" to the "out" department was counted as two persons and that the number of separate people receiving treatment should be greatly reduced. Much the same criticism is no doubt applicable to the reports of the other medical charities, and it is clear that the whole system of manipulating hospital statistics should be altered. Mr. Brocklehurst made various recommendations, such as that the medical charities should adopt a uniform plan of issuing their reports. Another suggestion was that care should be taken to ascertain the degree of indigence of the applicants for medical aid. He also proposes a central receiving hospital, to be called the Medical Clearing House. The idea is that patients should first go there and then be drafted off to the various hospitals according to the character of the case and the speciality of the hospital. These propositions look somewhat revolutionary, but a good deal may be said in their favour. The reports should be guiding, not misguiding. They should give the number of cases of treatment, the number of individuals treated, and the places where they come from. Mr. Brocklehurst said that, so far as he could gather from the reports, the Salford Royal Hospital alone had any organisation for getting this information. Some of the other hospitals, however, make use of the machinery of the Provident Society for this purpose. Mr. Brocklehurst thought that a third of the patients were able to pay moderate medical fees and should be sent on to the Provident Dispensaries. But these institutions are not very popular among the general practitioners nor, it is said, among the class of people who are urged to make use of them. The medical men not connected with them say that the dispensaries take their patients, often by touting and other underhand methods, and that while their members are indignant at the dispensaries being called charities they are bolstered up and supported by the subscriptions of the well-to-do, without which they would die from inanition; while their supposed lack of popularity with the "people" is said to be due to the attention given being too perfunctory. All this shows how difficult is the question of attendance on those who are a little too well off to be hospital patients. In the *City News* of Feb. 3rd Mr. Charles Behrens, the honorary secretary of the Provident Dispensaries, to prove their popularity states that according to the last report "22,119 members availed themselves of their advantages" and that 34 medical men are connected with the different branches. He also quotes a passage from one of the reports which gives quite a flattering pat on the back to the medical staff of that particular branch: "The committee have again the pleasing duty of testifying to the painstaking and skilful treatment by the medical officers of those members who have had occasion to avail themselves of their services." No doubt this was well deserved, for having accepted their positions the medical staff would do their duty. At the annual meeting of the Pendleton Branch, on Jan. 29th, the report stated that there was a falling off in membership from 3961 in the previous year to 3876, and Dr. A. Stewart, who has been a consistent advocate of the dispensaries while trying to get rid of their abuses, expressed surprise that in so populous a working-class district there was so comparatively small a membership. He accounted for it partly from the improvident habits of the poorer class and partly from the facilities for obtaining hospital treatment without charge, saying that there was much competition amongst the hospitals, each liking to show a large number of patients, as this encouraged substantial subscriptions. At this very meeting the chairman protested against the institution being called a charity, although it is well known that these dispensaries would not exist long without the support of the well-intentioned, but, as many practitioners think, mistaken, friends who give their help. Possibly as the result of the interest excited, some movement to avoid overlapping and to check abuse may be set on foot.

Feb. 13th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Epidemic of Influenza in Edinburgh.

DURING the month of January 41 deaths were register in Edinburgh as due to influenza and its various compli tions. The deaths occurred in persons over 60 years of a and the fatal cases appeared to have been almost entir confined to the districts of Morningside and the Gran In 1892, when there was a very severe epidemic of influe 45 deaths were recorded from the disease. In no year si 1892 has the mortality from this cause been so high a the present year. The poor parts of the city have in epidemic shown a remarkable freedom from the disease.

The Notification of Infectious Diseases in Edinburgh.

During the first half of the year 1899 the fees d medical practitioners in Edinburgh for the notificati cases of infectious disease amounted to £520 and i latter half of the year to £134 15*s*. During 1898 £35 was paid for the first six months and £542 7*s*. 6*d*. f latter half of the year.

Medical Officer of Health for the County of Sutherla

Dr. Patrick Murison (Dundee) has been appointed m officer of health of the county of Sutherland. Dr. M is a graduate of Edinburgh University and has b practise in Dundee for the last ten years. He is at pr magistrate of that city.

The Scheme for a Scottish Hospital in South Afri

A meeting was held on Feb. 9th in Edinburg Chambers to consider the scheme for the establish a Scottish hospital in South Africa. Lord Provost Thomson presided. The meeting was well attended siderable number of representative citizens being The Lord Provost explained that shortly after the scheme of the War Office for the accommodation of soldiers had been dropped he had been told pri General Chapman that the War Office authorities very grateful if the people of Scotland would gi hospital ship. He informed General Chapman th

---

[1] THE LANCET, Jan 27th, p 271

Lord Provost of Glasgow would enter into the scheme he would be glad to take the matter up. The Lord Provost and citizens of Glasgow, however, did not approve of the ship scheme in view of the amount of expenditure, £50,000 or £60,000, which it would imply. It had then been indicated to him by the War Office authorities that a very acceptable gift would be a hospital of 100 beds placed on the lines of communication and capable of being moved from place to place. The minimum sum for the equipment of such a hospital was £12,000, and he was glad to say that he had already received in all £6220 1s. from friends to whom he had applied The hospital would be used for the treatment of Englishmen, Irishmen, Welshmen, Scotsmen, and Colonials alike, but would be Scottish in other respects. The physicians and surgeons would be Scotsmen and the nurses would be from Scotland.' An executive committee was then appointed on which the medical profession is represented by Sir William Turner, Professor Chiene, and Dr. Joseph Bell. At the close of the meeting Sir William Turner moved a vote of thanks to the Lord Provost.

Aberdeen Royal Infirmary.

During last year 2516 patients were treated in the hospital, being a decrease of 89 compared with the previous year; but the number of out-patients rose from 5692 to 6625—an increase of 933. The annual report refers to the various efforts made to improve the finances of the infirmary, which resulted in an increase in the ordinary income of £1088. Legacies also showed an increase of £67, and notwithstanding the increase in the expenditure owing to the greater scope of the operations, higher rate of interest, increased cost of stores, &c, the deficit on the year's work was reduced by £467. The shortcoming, £785, it is remarked, is still formidable, but everything points to a nearer approximation of income to the needs of the institution. The number of cases treated in the Convalescent Hospital at Cults was 261, and the directors propose to take into the hospital a certain number of soldiers returned from the war suffering from wounds or illness.

Royal Asylum, Aberdeen.

The annual report by the directors shows that 185 patients were dischaged in 1899, as compared with 140 in 1898, there being 130 recoveries in 1899 and only 114 in 1898, while there were 16 more deaths last year than in the year preceding. The daily average of patients in the institution has increased by 48 4 The overcrowding, however, was partly relieved by the completion and occupation last spring of the laundry and workroom block for female patients, and within a few months two new wings at the hospital block will be finished Elmhill Cottage has meantime been made suitable for 25 female patients. The house of the medical superintendent has been enlarged at a cost of £450. The piggeries at the main asylum are to be removed to a site farther from the buildings. The new erections for the pigs will cost £500. The branch asylum at Daviot maintains its usefulness. For the year there is a surplus of income of £4175 2s over ordinary expenditure, £2000 of which is to be applied to the reserve for deterioration of buildings and furniture, and the balance in reduction of the cost of the extension and improvement scheme.

Feb. 13th

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Successor to the Registrar-General for Ireland.

MUCH interest has, of course, been excited among the medical profession as to the appointment of a successor to the late Dr. Wrigley Grimshaw, Registrar-General for Ireland. The most absurd reports on the matter have appeared in the local papers and indeed elsewhere Foremost amongst these wild statements was the announcement that Dr. J. W. Moore, President of the Royal College of Physicians of Ireland, senior physician to the Meath Hospital, and one of the best known physicians in Dublin, was a candidate. It would have been strange if a man of his position would accept such an onerous though dignified position for a salary reduced recently to £1000 a year. Dr. F. O. Martley, a graduate of Cambridge who is resident in Dublin, seems to be a likely candidate, for he has devoted much time to the study of medical statistics as his papers in the Transactions of the Royal Academy of Medicine of Ireland prove. The whole matter is, however, conjectural, and it is impossible even to say whether the precedent followed so recently in the case of the appointment of the new English Registrar-General may not be duplicated here by the choice of some layman.

Appointment of a Bacteriologist to the Local Government Board for Ireland.

A very important scientific appointment has just been announced. Professor E. J. McWeeney has been gazetted to the post of Bacteriologist to the Local Government Board for Ireland. This appointment means the establishment in Ireland of a scientific bacteriological department in connexion with the Local Government Board such as has existed in England for the last seven or eight years.

Royal University of Ireland.

The Senate of the Royal University of Ireland met on Feb. 8th and reappointed the various fellows, medical fellows, and examiners, there being very few changes of any importance. The following gentlemen were recommended to the Vice-Chancellor for nomination to the two commissions in the Royal Artillery placed at his disposal by the Secretary of State for War: (1) Mr. O. W. Nixon, (2) Mr. S. Perry, and in case either of these gentlemen fails to qualify, (3) H. J. Nolan-Ferrall.

Health of Belfast.

It was reported to the City Council on Feb. 7th that from Dec. 24th, 1899, until Jan. 20th, 1900, 69 deaths had been registered from zymotic diseases and 433 from chest diseases. The annual death-rate was 26 3. The cases of infectious diseases (scarlet fever, typhoid fever, and diphtheria) show a considerable diminution, and are generally becoming less numerous. The health of Belfast contrasts very favourably with that of most of the large towns of Ireland, and the death-rate (26 3) is very much lower than the average of the 23 principal towns therein (33 9). Owing to the epidemic of influenza the deaths from that disease are more numerous than in the corresponding month of last year.

Belfast and District Lunatic Asylum.

At the monthly meeting of the governors of the Belfast and District Lunatic Asylum, held on Feb. 12th a report was read from the Government inspector (Dr. G. P. O'Farrell) in which he stated that notwithstanding the fact that 185 patients had been transferred to the new County Antrim Asylum, there was no corresponding diminution in Belfast Asylum, so great has been the influx of patients. Of the 902 patients on the register 241 were chargeable to the county of Antrim and 661 to the city of Belfast. The plans for the new Purdysburn Asylum had been referred for report to Mr. Hine, consulting architect to the English Lunacy Commissioners. The joint finance and asylum sub-committee, after considering this report, recommended *inter alia* that the asylum should comprise two separate buildings for the different classes of patients—one a reception hospital for mental diseases and the other the asylum for chronic cases, and that such reception hospital need not provide for more than 150 patients. Dr. O'Farrell in his report congratulated the board of governors on the marked progress which, apart from its structural defects and overcrowding, the asylum continued to make.

The Battle of the Clubs at Cork.

In these notes I have pointed out more than once that the local press is hostile to the contention of the local profession to an extent that outsiders could hardly realise and one that is not at all justified by the real state of affairs. It is therefore very satisfactory to be able to chronicle that the *Cork Evening Special* not only publishes *in extenso* the very able report of THE LANCET Special Commissioner, but devotes a leading article to the subject which is distinctly sympathetic in its tone. The *Cork Evening Special* heads its article, "The Doctor and his Fee." Alluding to the report of your Commissioner it says.—"We transfer the article to our columns to-day for two reasons. One is that the *résumé* appears to be an impartial version of the entire dispute, though written, of course, from the professional standpoint. The other is that the history of the affair is brought up to date, and therefore covers a period with the incidents of which the general public are not acquainted. As regards what is left of the dispute we will not enter into a discussion of the merits of the case. Now that feeling has cooled down, so to speak, it hardly seems worth while to keep up the little friction that remains any longer. If the publication of The Lancet article in our columns, where it will come under the notice of the general public, will help to bring about a complete restoration of peace it will serve a useful purpose."

The Treatment of Dyspepsia by Natural Gastric Juice.

An important discussion has been occupying the attention of the Therapeutical and the Hospitals Medical Society for several sittings, the subject being a new method of treatment introduced by Dr. Frémont of Vichy. In his first paper on the subject he cited the case of three patients reduced to the last stage of cachexia who were saved by the administration of from 100 to 150 grammes of gastric juice given in divided doses of 25 grammes mixed with 75 grammes of cold milk, beer, or bouillon. If hot milk were used one single indigestible clot formed, but if the milk were cold numerous small clots formed which were easy of digestion. With beer as a vehicle an agreeable liquid with a slightly acid taste was obtained. If bouillon were used it should be cold, since the ferment was destroyed by hot bouillon. The duration of the treatment had to be regulated by the progress of the general health. The end to be sought was the gradual withdrawal of the gastric juice until the patient arrived at a stage at which he could do without it altogether. The treatment is contra-indicated in cases of hyper-secretion or cancer of the stomach. The undeniably good results obtained by this treatment cannot be explained away as being due merely to suggestion, for upon patients learning the nature of the fluid which they are taking they exhibit disgust and the good effects of the treatment become less apparent. Dr. Frémont has therefore taken to calling the gastric juice *gasterine*. The treatment is unhappily not within the reach of all purses, for in order to provide the large doses necessary a regular pack of small dogs with gastric fistulæ has to be kept so as to provide the necessary amount of gastric juice This difficulty was specially dwelt upon in the discussions on the paper. Nearly everyone, however, and especially those physicians most experienced in the treatment of dyspepsia such as Albert Robin, Mathieu, Huchard, Bardet, Linossier, and Legendre, recognise that the treatment adopted up to now of giving hydrochloric acid and pepsine has only given illusory results owing mainly to the far too small doses given. M. Linossier remarked that patients suffering from a deficiency of gastric juice might show a deficiency of acid to a degree of as much as 20 grammes below the normal. The strength of the average dose prescribed is four grammes to the litre, a strength very much below that of normal gastric juice. The same holds good with pepsin. The daily secretion of this by the stomach corresponds to 325 grammes and the amount generally given as a drug rarely amounts to more than from a half to one
gramme a central [illegible] considered that pepsins much more

should be guiding, not misguiding. They should grined
number of cases of treatment, the number of individuals treated, and the places where they come from. Mr. Brocklehurst said that, so far as he could gather from the reports, the Salford Royal Hospital alone had any organisation for getting this information. Some of the other hospitals, however, make use of the machinery of the Provident Society for this purpose. Mr. Brocklehurst thought that a third of the patients were able to pay moderate medical fees and should be sent on to the Provident Dispensaries. But these institutions are not very popular among the general practitioners nor, it is said, among the class of people who are urged to make use of them. The medical men not connected with them say that the dispensaries take their patients, often by touting and other underhand methods, and that while their members are indignant at the dispensaries being called charities they are

pepsina amylacea. Under these circumstances he thought that albuminous fluids with the proper proportions of acid and pepsin would give the same results as gastric juice. Professor Hayem remarked that the gastric juice obtained from dogs by Dr. Frémont differed considerably from normal gastric juice. It was hyper-acid and the acidity was due to free hydrochloric acid. It was, therefore, according to Professor Hayem, merely a rather strong solution of hydrochloric acid. In the preliminary operation Dr. Frémont divides all the branches of the pneumogastric nerve supplying the stomach, which has the result of rendering the gastric juice free from pepsine. It is a difficult operation and many animals die. Professor Hayem has tried this gastric juice treatment in the cases of a certain number of patients who were apparently none the worse. He concludes, therefore, that Dr. Frémont had given himself a great deal of trouble for very little result.

Obituary.

The death is announced, at the age of 53 years, of Dr. Gombault, physician to the hospitals. The death is also announced, at the age of 90 years, of Professor Tourdes, honorary dean of the Faculty of Medicine at Nancy. He was especially noted for his work in forensic medicine.

Notes on News.

The election of a member of the Academy of Medicine to fill the place in the section of obstetrics vacant by the death of Dr. Charpentier, which occurred last year, has resulted in the election of Dr. Champetier de Ribes, obstetric physician to the Hôtel Dieu, by 34 votes, as against 33 given to Dr. Doléris, obstetric physician to the Boucicault Hospital.

(From our own Correspondent.)

Professor Kronlein on Cancer of the Rectum.

On Jan. 31st Professor Kronlein of the Zürich Surgical Clinique delivered an instructive lecture to the Clinical Society of Zurich. He first showed two patients, aged 26 and 31 years respectively, who had been operated upon successfully for cancer of the stomach. He wished to lay especial stress on the fact that gastric trouble in young subjects did not exclude the possibility of the existence of a cancerous growth. He then spoke on cancer of the rectum, basing his remarks on an experience of 19 years, pleading for early diagnosis and contradicting a pessimism which still pervades the profession with regard to operative results. In the canton of Zürich, with a population of 345,000, the average annual number of deaths is 6154, 4043 of which refer to people over 25 years of age. Of this latter number 10 9 per cent., or 442 per year, are due to cancer. Whereas cancer of the stomach averages 49 3 per cent. of all cancers, the cancers of the breast and those of the intestinal tract number only 4·6 and 4·7 per cent. respectively. Out of 22,760 hospital cases under Professor Krönlein's care from 1881 to 1899 there were 1305 cases of cancer, 101 of which referred to cancer of the rectum. Add to these nine cases from private practice and the number of 110 is obtained on which he bases his deductions. The age varied from 26 to 78 years, the number of males being in excess of those of females as 17 to 10. Hæmorrhoids could not be considered as a determining [illegible] factor, but the number of cases from tuberculous

to eight years, which contrasts favourably with the average life of one and a half years in cases that go without operation. Ten cases had remained free from disease for from three and a half to 12 years. The functional results depend on the extent of the cancer and the operation, and were good in 45 per cent of the cases, indifferent (partial insufficiency) in 40 per cent , and bad (total insufficiency) in 15 per cent. of the cases that underwent operation.

Roentgen Rays and Renal Calculi.

Dr. E. Tschudy of Zürich reports an interesting case of nephrolithiasis. The case occurred in a woman, aged 30 years, who had suffered for one year from pyelitis which, as cystoscopic examination proved, affected the right kidney. Nephrotomy was performed in March, 1898; the renal wound was closed by deep sutures after removal of a renal calculus. The patient was dismissed relieved in May, 1898. Recurrent symptoms took the patient to Wildungen in the summer and autumn of 1898, and examination in June, 1899, proved that the urine of the right kidney was normal, but that the left kidney was affected by pyelitis. After several attempts Mr. Wuest of Aarau succeeded in producing a Roentgen ray photograph demonstrating the presence of a renal calculus. Nephrotomy was then performed on the left side on June 27th with success and the patient was dismissed on August 9th. She feels well and has no renal symptoms; but microscopic examination of the urine still reveals an irritative process of the kidney. Roentgen rays promise to aid the surgeon to an early diagnosis in cases of renal calculi, which are very rare in Switzerland.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Small pox.

UPPER Italy, Central Italy, and Southern Italy are all of them visited by small pox—the numerous cases registered at Acqui in Piedmont having been followed by others at Comacchio in the Ferrarese, at Florence, and at Gaeta. The majority of these are of the confluent kind, or, in Italian parlance, "vaiuolo nero". (black small-pox); but as to Florence it is right to say that they have been, and still are, "benignant" or non-confluent. The Florentine prefect writes "In this province, out of five cases of 'benignant' small-pox one has been followed by death due to intercurrent pneumonia. It frequently happens in such cases that small cutaneous hæmorrhages appear which have no specially grave significance, but which, by the lay public, are easily confounded with 'vaiuolo nero.' All the types of small pox have one origin and one only—to wit, an infective origin—and the manifestation of benignant small-pox or of 'black' (confluent) small-pox stands in essential relation with the practice or non practice of vaccination and revaccination, and with the interval, shorter or longer, that has intervened from the last inoculation." It is from France that the disease has been introduced and, as I have said, stringent measures are being enforced at the frontier to check its further importation. At Florence, moreover, every effort is put forth to isolate the disease—a lazaretto having been specially organised *ad hoc.*

Italy and the Wounded from South Africa

Not only in the lake country, not only on the Riviera Ponento and Levante, are hotel keepers putting their houses at the disposal of wounded or convalescent officers from South Africa, but further south the same kindly hospitality is daily *en évidence*. I have mentioned the "Albergo delle Sirene" at Porto d'Anzio as having followed the initiative of the Alta Italia, and now I must add to the list the well-known Hotel Tramontana at Sorrento, the accommodation and advantages of site and climate of which have been liberally devoted by the landlord to the same beneficent purpose.

Sanitary Precautions at the French Frontier.

This has been a bad, almost a disastrous, season for the hotels and for all the interests that depend on the sojourn of visitors or "paying guests," and yet so alive is the Government to the danger of reinforcing the infective diseases now *en évidence* throughout Italy that it is adopting the most stringent measures which may still further exclude the outside world, comprising the "paying guests" aforesaid. This in the long run is the best, because it is the "honest policy," and Italy in future years will profit by the reputation she will have won for preferring the "salus populi" to immediate pecuniary gain. The following is the official ordinance issued by the Government for the protection of the Italian public against insanitary importations at the French frontier:—

Article 1st.—All persons proceeding from Marseilles and travelling "in carovana" (in companies) by land, on their arrival at the first railway station of the Italian Kingdom, will have to undergo a medical visit, and should the sanitary officer charged with its performance find it necessary they will have also to undergo the disinfection of their appurtenances whether of personal or common use.

Article 2nd.—Provision will further be made (*a*) for the sending of suspected cases, under due precautions, into the *locale* of isolation belonging to the commune in which the railway station is situated; (*b*) for the vaccination of all persons who do not present the obvious, recognisable marks of recent vaccination; and (*c*) for the diligent disinfection of the carriages in which the said cases have been travelling.

Illness of Dr. Baccelli.

The Minister of Public Instruction, whose convalescence from influenza I recently announced, has had a relapse, due, there is no doubt, to his imprudence in returning to the cares of office when he should still have kept within doors. These cares have been aggravated by the turmoil and insubordination now prevalent at the universities, chiefly Naples and Padua, causing animated "interpellations" in Parliament and involving his Excellency in vivacious controversy with such formidable antagonists as Professor Cardarelli and Professor D'Ancona. Remanded perforce to bed, he has had to delegate his parliamentary duties to Signor Manna, Under Secretary of State at the "Minerva," as the Education Office is called; and now I hear that this functionary, too, is ill and cannot appear—the "hidden Manna," as a Deputy with more *esprit* than reverence calls him. For the moment public instruction is, officially speaking, in "suspended animation," *àpropos* of which the following epigram has been going the round of both Houses, Upper and Lower:—

> Aegrotus Baccellus abest; quoque Manna laborat,
> Morbo nostra malo tota Minerva perit.
> (Baccelli's ill and Manna follows suit,
> And so our whole Minerva plays them ute)

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Antirabic Institute.

A YEAR ago Dr. Tonin, who has made a special study i the institutes of Turin and Naples, opened an antirabi institute in Cairo. Until that time individuals bitten by ma animals had to proceed at their own or at the Governme expense to Paris or Athens for treatment. Naturally it sometimes happened that this delay proved fatal, so the Italian Benevolent Society were delighted to place a room at Dr. Tonin's disposal. He has now issued a report of 10 months' work and has had 86 patients sent to him. Of these nine were bitten by animals proved to be not mad and there therefore remain 77 to be considered. Of these 62 were Egyptians, five Germans, five Italians, four Greeks, and one was a Frenchman. 10 were bitten by wolves, six by cats, one by a jackal, and one by a hydrophobic woman at the native hospital The remaining 59 were bitten by dogs in the proportion of seven European dogs to 32 native pariahs. 24 of the cases were diagnosed as certain rabies by experiments on rabbits. In four other cases an absolute diagnosis was made in writing by the veterinary surgeon who diagnosed rabies in the living animal, and the remaining 49 were cases in which rabies was strongly suspected. All the patients who completed the routine treatment are now healthy and well, but seven of the 10 wolf bites developed hydrophobia during the antirabic inoculations and died at Kasr-el-Aini Hospital. All these unfortunately began their treatment more than 10 days after being bitten and they exemplified the usual circumstance that patients with wounds in the face or head were earliest affected. In two of the hydrophobic cases intravenous injections were tried without avail Attention is thus drawn to the fact that rabies and hydrophobia certainly exist in Egypt. During by Mr. Knaggs to which I have already referred is a most admirable example of this.

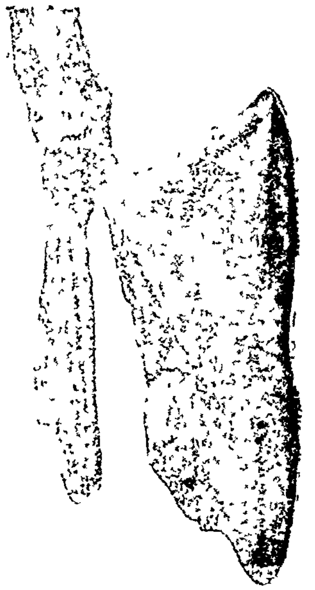
ETIOLOGY OF INTERSTITIAL HERNIA.

Much that has been said of properitoneal hernia applies with equal weight to interstitial hernia. The pouches of Rokitansky and of Aschoff cannot, of course, stand in any causal relationship. The portion of the funicular process from which the diverticular sac is formed is either the "third portion" of Eppinger or the portion immediately outside the external oblique. The anomalies of the testis are noticed with even greater frequency in interstitial than in properitoneal hernia. Of 129 cases tabulated by Macready in 73 4 per cent. there was some abnormality of the testis and in 67·1 per cent. the testis was either completely retained or had only partially descended. In 28 cases the testis could not be found at all. This form of hernia is, however, of decidedly greater relative frequency in females than in males. Macready gives the percentage as 0 13 per cent. for males and 0 61 per cent. for females. The same preponderance of cases on the right side is also noticeable.

The most satisfactory explanation of the development of interstitial hernia is, I venture to think, founded upon the connexion of the hernia with retained testis. The testis bars the way to a further descent of the hernia and the inguinal portion of the sac bulges out in the direction of least resistance. This explanation is strengthened by the observation, which is almost universal, that the scrotum is hardly ever fully occupied by a sac containing bowel or omentum. As a general rule the lowest point reached by the descending hernia is at or just outside the external abdominal ring. An exquisite example of this is found in the Guy's Hospital Museum, No. 1120. The bulging sac behind the barrier-like testis held "nearly a foot of ileum." In 129 cases observed between 1866 and 1890 at the Truss Society in nine only was the scrotum occupied by the hernial swelling. If the testis has not passed clear of the external ring the scrotum is ill-developed, but "a flat band of tissue, the remains of the gubernaculum, can generally be traced passing from the canal over the crest and body of the pubes" (Macready).. In some cases, however, the testis is normal in position and the explanation just given is therefore inapplicable to them and to the cases occurring in women. There is one explanation, however, which, although I do not think it adequately accounts for these cases, is still deserving of recognition. In the earlier records there is occasional mention of the "thinness" of the abdominal wall in the inguinal region, of "obliteration of the layers," and so forth, but, so far as I am aware, it is to Macready that we owe the assertion of the importance of this condition. He has shown that "the wasting or congenital defect of the muscles is chiefly noticeable below a horizontal line through the anterior superior iliac spine. It concerns sometimes the external oblique as well as the deeper muscles. In a greater or less degree it seems to be a constant feature in the interstitial hernia now under consideration." I cannot do better than quote the following passage from Macready's "Treatise on Ruptures": "If we seek for the principal difference between interstitial and those herniæ with anomalies of the testis we find it in the condition of the parietes. I have drawn attention to the delicate membranous state of the abdominal walls about the inguinal region. Here is a difference between interstitial and other herniæ which is common and which is real. If the imperfection of the abdominal wall, so often noticed with these herniæ as existing in greater or less degree, is their original cause, it does not militate against the supposition that a large proportion are attended with anomaly of the testis. On the contrary, when that organ is defective it is very probable that the parts through which it passes and with which it is so intimately related will be likewise deficient, more especially as the anomaly of the testis in these cases is generally of a high grade." It must, however, not be forgotten that this muscular atrophy and thinning may in some cases be the result rather than the cause of the hernial formation. The weight of a large hernial mass constantly pressing unduly on the muscular wall may lead to its wasting or disappearance. Macready does not bring forward any arguments in support of his views which seem to me convincing. I should certainly be disposed to consider the wasting of the muscles which undoubtedly exists rather as an effect than as a cause of the hernia.

In that class of case where the hernial sac lies between the external and internal oblique, if the external muscle be firm and the internal and transverse be thin and atrophied the resistance met with at the external ring would cause a bulging beneath the aponeurosis of the external oblique. The condition in which the sac lies upon the external oblique may be caused by a testis retained immediately outside the canal, or possibly by the misapplied pressure of a truss, apart altogether from any irregularity, congenital or otherwise, in the muscular layers. The records of the cases show that in almost all of them the internal and external rings are opposite one another, forming practically one large opening. The sac can readily enough leave the canal therefore. The obstruction to its downward tendency must then arise external to the ring in one or other of the ways suggested. A study of the peritoneal conditions existing in properitoneal hernia suggests a close relationship between this form of hernia and the condition described as "bilocular hydrocele" (Fig. 6). If we suppose that the ostium abdominale becomes closed (by the normal process of "physiological agglutination") and that fluid collects in the inguinal and properitoneal sacs we *should have then a* hydrocele of the tunica vaginalis communicating with a serous cavity lying in the abdomen between the peritoneum and the fascia transversalis. That is precisely the condition found in bilocular hydrocele. A reference to the recent case reported by Felix von Winiwarter shows that the conditions found in the removal of the sac of this form of hydrocele are the same as in properitoneal hernia save that in the former the mouth of the sac (ostium abdominale) has closed and fluid has collected in the serous cavity and in the latter the mouth has remained open and a hernial descent has occurred.

FIG. 6.



Bilocular hernial sac "Two thin membranous sacs, communicating with each other and having a common opening at what appears to be the internal abdominal ring The sac contained a hernia and a quart of 'ascitic' effusion" The identity of this condition with bilocular hydrocele is at once apparent. (Guy's Hospital Museum, No. 1159.)

SYMPTOMS AND SIGNS: PROPERITONEAL HERNIA, INGUINAL.

With the rarest exceptions cases of properitoneal hernia are first seen when symptoms of acute or sub-acute strangulation are present A patient who for years has had a hernia for which, perhaps, a truss has been worn begins acutely to suffer from symptoms of obstruction. The hernia may be found on examination by the surgeon, taxis may be applied, and the hernia with little difficulty reduced. Symptoms of strangulation persist and steadily increase and operation is resorted to, or the patient dies and the condition is revealed. In some cases—a minority certainly—some swelling may be noticed *after* the reduction of the hernia; a "sausage-shaped swelling reaching the anterior superior spine" has been more than once recorded. But in most cases no swelling is seen and an examination of the specimens in the London museums explains that. As I have already described, the properitoneal sac may pass outwards, backwards, or inwards and downwards. If outwards a swelling or an indefinite though appreciable tumefaction may be caused; if backwards there will be probably no swelling; and if inwards and downwards there will certainly be none. Kronlein figures one case in which the tumour on the outer side of the canal is well shown. Since this author drew special attention to this point more accurate examination has revealed a tumour in the majority of cases. Thus, in Breiter's 36 cases a "tumour or tumefaction" was present in 22. In only eight of the cases is it definitely asserted that careful, purposeful examination revealed no bulging. Judging from museum specimens I should decidedly say that in the great majority no swelling could have been revealed during life. The cases where swelling is absent are less likely to be correctly diagnosed; the result, therefore, is that such cases are more likely to die and the specimen reach the museum. Breiter's proportion of 22 out of 36 is therefore very considerably in excess of the truth.

Strangulation of the contained omentum or bowel may occur in one of three places: (1) at the ostium abdominale, the common orifice of the two sacs into the peritoneal cavity; (2) at the neck of the properitoneal sac; and (3) at the neck of the inguinal sac. If at 1 the bowel or omentum may be "reduced" from one sac to the other, remaining strangled at the ostium abdominale; if at 2 there may be no signs and symptoms but those of acute obstruction, and attention may never be specially called to the inguinal region; and if at 3 the case clinically is a strangulated bubonocele or scrotal or femoral hernia. In some few cases, according to Breiter, it has been observed that when two sacs are clearly present reduction of the hernial contents from the outer one causes an immediate and concomitant bulging of the inner sac, and *vice versâ.* The symptoms of strangulation are, one gathers from the record of the case, neither so sudden in onset nor so swift in their increase as in the ordinary strangulated hernia As a result operation has frequently not been resorted to till the sixth, eighth, or tenth day. In some of the records I have noticed that "vermicular contraction" of the intestine, "coiling," and "hypertrophy" are mentioned. This would seem to indicate that some obstruction has been of long duration. The sudden stoppage of the intestine by any cause, internal strangulation, or strangulation in a hernial sac never, in my experience, causes any such condition of hypertrophy as is here referred to. A hypertrophied intestine, the contraction of which can be seen through the abdominal wall, giving rise to "coiling" and "vermicular contraction," must inevitably be the result of long-standing and either intermittent or incomplete obstruction. In properitoneal hernia the ostium may be the cause of the partial or temporary obstruction. Almost all the museum specimens that I have examined are to be found, not under the heading of "properitoneal hernia," but under "reduction in mass." The symptoms, therefore, are in a large number of cases those of the latter condition. To this point I shall refer again So far as the contents of the sacs are concerned there is little to remark. In three-fourths of the cases small intestine alone is present; the omentum, large intestine, and in one case the cæcum have all been noticed. Three of the cases are said to have been examples of what is commonly, though unreasonably, termed "Richter's hernia." Crural properitoneal hernia is much rarer than the former. Breiter records only nine cases, four on the left side, three on the right, and two undetermined. The average age of the patients is higher by several years than that of the inguinal variety The external swelling is invariably small and the obstruction has always been furnished by the ostium abdominale.

DIAGNOSIS.

As can readily be understood the diagnosis of properitoneal hernia before operation is sometimes a matter of difficulty or is even impossible. In cases where a swelling, bulging, or tumefaction is noticed the diagnosis can be and has been accurately made. Such cases should offer no difficulty to a careful observer The frequency of the association of testicular anomalies should make the surgeon prompt to investigate the precise nature of any hernial swelling where the testis is not in its normal position, especially on the right side. If, however, there is no inguinal swelling the symptoms are those of "reduction in mass," of acute obstruction, not, as a rule, of the most violent type.

SYMPTOMS AND DIAGNOSIS OF INTERSTITIAL HERNIA.

In interstitial hernia the mural sac is always capable of being recognised. At one time or another the sac can be seen distended with the usual hernial contents and no difficulty can be experienced in the recognition. The symptoms are generally inconspicuous and strangulation is infrequent.

TREATMENT.

Only one treatment can possibly deal effectively with properitoneal and interstitial hernia—operation. The wearing of a truss is useless and in most cases must also be a source of positive harm. The whole of both sacs should be excised, an undertaking which will involve a certain amount of division or separation of muscular and tendinous fibres. The "radical cure" can be afterwards carried out by any of the methods suited to the occasion. In some cases the removal of the testis is desirable. If it is retained in or immediately external to the canal it will suffer from the pressure of a truss if one has subsequently to be worn. A retained testis is, moreover, a source of some danger in any case. It is liable to suffer from inflammatory conditions or malignant disease; and as its usefulness is doubtful there can be no valid reason for allowing it to remain. In order to get at the second sac without a further incision than is needed for all herniotomies Baron suggests that when the outer sac is stripped to its neck a vigorous traction should be applied. The result will be that the ostium abdominale will be brought into view, any strangulation there can be relieved, and the bowel returned; subsequent removal of the inner sac if small is then possible.

In certain recorded examples of inguino-properitoneal hernia the neck of the sacs has been so high up that to reach it a formidable incision in the abdominal wall would have been needed. Operating under such conditions, Trendelenburg, Ward, and Lawson Tait have suggested and adopted the median abdominal incision—have, in fact, dealt with the case as one of intestinal obstruction. This procedure is certainly much simpler, probably very much safer, and, if recovery follows, less mutilating and disabling, than the older method of "hernio-laparotomy."

PROGNOSIS.

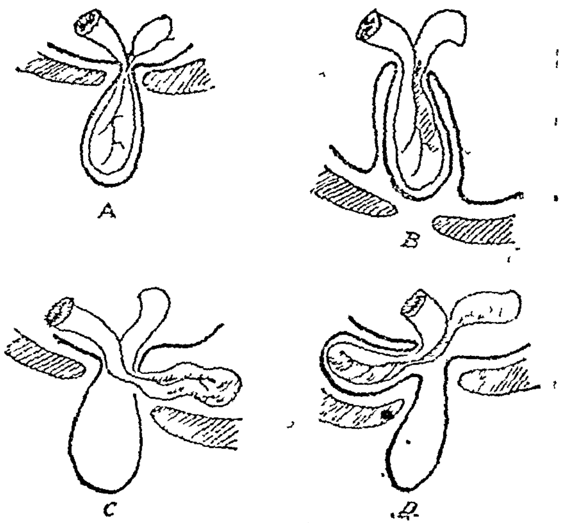
The prognosis is always serious in cases where symptoms of acute or sub-acute strangulation are present. There are the usual dangers of strangulated hernia, and in addition the danger accruing from insufficient evidence upon which to found an accurate diagnosis. There may be a quite gradual development of the symptoms of strangulation and operation is in consequence delayed in many cases. Moreover, the apparent reduction, reduction in mass, is misleading. There are not sufficient cases in recent years to make any statistics that may be compiled of the least value. The prognosis may perhaps be most aptly expressed by saying that the risks are slightly but appreciably greater than those of strangulated hernia.

REDUCTION IN MASS

I have already remarked that my observations have led me to conclude that many cases of "reduction in mass" are in reality cases of properitoneal hernia. "Reduction in mass" has been described as being the result either of a complete return of the hernia, sac and contents, undisturbed *so far* as their mutual relations are concerned, within the abdomen, but outside the peritoneum; or of a rupture at the neck of the sac by which the hernial contents escape *from* the sac into the lax subperitoneal tissue still strangled at the neck. I once operated upon a man suffering from strangulated inguinal hernia whom I believed to have suffered from a reduction in mass. On cutting down to the sac I found it quite flaccid and loose and I discovered a rupture in the sac near the neck through which all the fluid of the sac had escaped, leaving the bowel a mere knuckle lying undisturbed within the sac. I find that Birkett describes three similar cases; Streubel refers to three and Maydl has observed two. If the hernia be small and the patient stout the dispersion of the fluid will give an appearance of reduction whether the fluid has escaped subcutaneously or into the subperitoneal tissue. A rupture of a vaginal hydrocele under pressure applied too vigorously by the patient has been not infrequently recorded.

In searching the museums of London for examples of properitoneal hernia I was at once struck by the fact that the great majority of the specimens were described as "reduction in mass." Thus, in Guy's Hospital Museum specimens 1134, 1135, and 1143, and in St. Bartholomew's Hospital Museum specimens 2117 and 2118, are so labeled. Specimen 2118 (St. Bartholomew's) is a remarkable example of the inward and downward projecting pouch which reaches the bladder. A careful examination of each of these specimens shows indubitably that there is no rupture at the neck of the sacs, but that the bowel, strangled at the ostium abdominale, has passed from an inguinal sac to the properitoneal one, the serous lining of which is quite clearly recognisable. A similar example in a case of cruro-peritoneal hernia is shown in Specimen 1143 of Guy's Hospital Museum. The impression gathered from museum specimens alone is that the very great majority of examples of "reduction in mass" are in reality no other than cases of properitoneal hernia in which the bowel has been reduced from the one sac to the other. An attempt to gauge the relative frequency of these conditions based upon museum preparations alone is necessarily unsatisfactory. Only the severer cases are there represented. Cases successfully dealt with by operation may be recorded by the surgeon, but his account, however precise, reveals a lack of that intimate acquaintance with the circumstances which a careful dissection is alone capable of giving.

FIG. 7.



Reduction in mass.

Reduction in mass may therefore be described as of the following varieties. 1. Reduction into a sac lying between the peritoneum and the transversalis fascia (Fig. 7, D). This sac has probably received the bowel on many previous occasions. It exists in both the inguinal and femoral regions, forming the special class of hernia known as properitoneal or bilocular. This sac may pass (*a*) inwards to the bladder, (*b*) backwards to the iliac fossa, or (*c*) outwards towards the anterior superior spine. This form is probably by far the most frequent. In a very few cases, not five in all, the apparent reduction has occurred into one of the interstitial sacs beneath or superficial to the external oblique. Such a case was that under the care of Mr. Cock (Guy's Hospital Museum, No. 1120). 2. Reduction of the whole sac within the abdomen but outside of the peritoneum, the relations of sac and contents to one another being unaltered and strangulation at the neck still persisting. (Fig 7, B) It is probable that the loosening of the sac is of long duration and is the result of vigorous and ill-regulated taxis. This variety is rare. It was first described by Saviard, afterwards by Le Dran, Lafaye, and Richter. 3. Rupture of the neck of the sac and escape of the contents of the sac through the rupture into a cellular space outside of the peritoneum (Fig. 7, C). The rupture generally occurs at the back of the sac just below the neck. This form of reduction has been well described by Birkett. If fluid alone escapes while the bowel remains an illusory appearance of reduction will be presented. It might be worth while to emphasise this condition as "false reduction in mass," for clinically the two conditions of "false" and "true" reduction may be precisely similar. If in "false" reduction the rupture is at the distal extremity of the sac and the discharge of fluid subcutaneous it is impossible, of course, for bowel to escape. As a variety of this form may be mentioned the passage of the strangled intestine through a cut made near the neck of the sac when a hernia knife had been introduced to divide the "stricture at the neck of the sac." Maydl has observed this accident. After the supposed division of the strangled band pressure is applied to the bowel and reduction apparently occurs. The neck of the sac is, however, untouched and the strangulation consequently persists. A very beautiful example of this kind is recorded by Farabœuf. This form also is rare.

A fourth form of "reduction in mass" is described and figured by Roser and mentioned by Pick. It consists in the reduction "into the inguinal canal" of the bowel that has formerly occupied the scrotum. A wide dilatation of the canal is considered as permitting this partial reposition. I have not been able to discover a museum specimen of such a condition, nor have I found any unequivocal case in the literature of this subject, though mention of the condition is made by several of the earlier writers on hernia. Chelius considered that in herniæ of moderate or large size when reduction was apparently complete a small segment of gut, thick with inflammatory products and paretic, might lie inert in the canal and undergo a later, secondary strangulation. Reduction of the strangulated contents of a hernial sac into a second underlying sac in the scrotum have been recorded by Armand, Horn, Sandyfort, and Scarpa. It is possible that these second sacs are pulled down into the scrotum by gubernacular bands, in the same manner as the sac of an infantile hernia. Demmeaux has suggested that whether the sac first present in the scrotum be congenital or acquired the press of intestine on a weak and loosely supported neck may cause a diverticulum slowly to develop. Such pouch may be in front or behind, to the inner or outer side. If rupture of the neck of a femoral sac occurs the bowel may pass into the subperitoneal tissue. Callisen recorded in 1777 a case where, owing to rupture of the sac below the neck the bowel had escaped and made for itself a lodgment between the pectineus and psoas muscles. These conditions may be represented in tabular form thus:—

True reduction in mass.—1. Reduction into a properitoneal sac; rarely an interstitial sac. 2. Reduction of the whole sac with contents within the abdomen outside of the peritoneum, the mutual relations of sac and contents being undisturbed. 3. Rupture of the neck of the sac or its division during operation and extravasation of the hernial contents into the subperitoneal tissue.

False reduction in mass.—1. Rupture of the sac at the neck or elsewhere with escape of fluid only. The hernial swelling becomes considerably smaller, but the bowel remains strangled. 2. Reduction of part of the hernial contents. A small portion remaining in the canal, paralysed and stiff with inflammatory products, undergoes a "secondary" strangulation.

LECTURE II.

Delivered on Feb. 21st.

ENCYSTED HERNIA.

MR. VICE-PRESIDENT AND GENTLEMEN,—The term "encysted hernia" is one which for well nigh a century has been the subject of abuse. There has long been, and there still continues to be, much difference of opinion as to the most apt and appropriate names for some of the less common forms of hernia. The term "infantile," introduced in the year 1803 by the first William Hey of Leeds for a certain condition of hernia which it in no sense accurately described, has recently been appropriated by Lockwood for that variety of hernia in which a separate peritoneal pouch is dragged down into the scrotum probably by an aberrant attachment of the gubernaculum. The majority of surgeons who have written since Lockwood's admirable work was published have accepted, unhesitatingly and with complete accord, his description of that hernia and his restrictive adoption of the term "infantile" for it. I propose to retain the term "encysted," which is strikingly appropriate for that variety of hernia which Hey described and figured and which Cooper subsequently verified I would define encysted hernia, therefore, as that form of hernia in which the sac, with its contents, wholly covered on the outer side by a reflected layer of serous membrane, hangs downwards from the internal ring in the cavity of the processus vaginalis The portion of the processus vaginalis containing the hernia may be the whole as far upward as the internal abdominal ring, or may be only the upper portion, that lying in the inguinal canal along the cord, the lower portion, tunica vaginalis, having in this case been shut off by the ordinary fusion process occurring at the upper end of the testicle This form of hernia, from some misconception which I do not understand, has not received adequate recognition from the later English authorities Macready in his work on "Ruptures," mentions encysted hernia only in a footnote, which is very brief, but is at least of sufficient length to show that he does not appreciate this variety Lockwood who has contributed by far the best work on hernia of any English authority of recent years, in defining and describing "infantile" hernia, had overstepped, as I think, the very definite boundary between infantile and encysted herniæ and has made an attempt to include some of the latter among examples of the former Birkett in his article in Holmes s System gives a good account, based upon Forster s observations, of one form of this hernia Other authorities either ignore the subject or quote without question the work of one or other of the writers whom I have named

HISTORY

The first case of this kind is probably that which occurred to *Mèry at the Hotel Dieu in 1701* *Forster s* case, recorded in Sir A Cooper's work is described as follows "A shoemaker, aged 31 years who died of strangulated hernia, on dissection the following were the appearances When the scrotum was divided the tumour was brought in view, taking the course of the *spermatic cord, evidently* involved with it, and much contracted at the ring On investigating further and cutting carefully through the tunica vaginalis of the cord near the ring a fluid escaped I then continued the incision to the bottom of the scrotum, through the tunica vaginalis of the cord, and the tunica vaginalis testis, which I now found to be one cavity, the edges of which being turned back on either side exposed a hernial sac pendent from the ring and descending towards the testicle From hence it evidently appeared that the hernial sac and its contents were contained in the tunica vaginalis of the spermatic cord, which formed only one cavity up to the ring On opening the hernial sac it was found to contain a portion of small intestine of a claret colour and in a mortified state" At Hey s request the specimen from this case was examined by Sir A Cooper and Mr J Pearson, and the following was their report —

"In consequence of Mr Hey having expressed a wish that the encysted hernia of the tunica vaginalis *taken from* a patient of Mr Forster s in Guy s Hospital and preserved in the museum of St Thomas s Hospital should be carefully examined,

"We, the undersigned, have inspected the preparation above mentioned with much care, and the result of our inquiry is —

"1 That the bag in which the intestine is incarcerated hangs within the tunica vaginalis testis, and reaches nearly to the superior edge of the epididymis

"2 The only connexion which this bag has with the tunica vaginalis is at its orifice, at which part it adheres firmly to the tunica vaginalis

"3 *From this adhering portion the bag hangs* like a pear depending from its stalk within the tunica vaginalis

"4 The tunica vaginalis forms a smooth unbroken surface as usual "&c, Signed,

"ASTLEY COOPER,
"JOHN PEARSON"

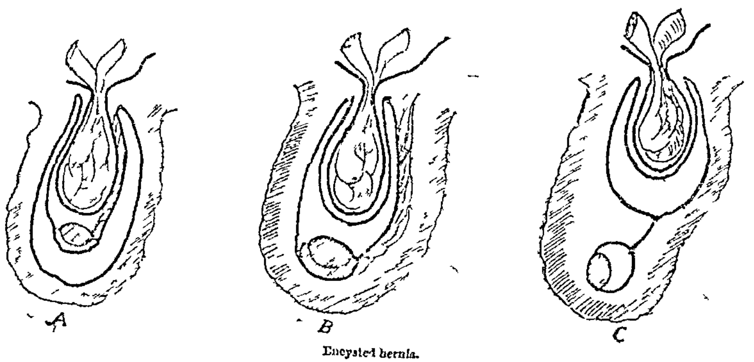
Dupuytren and Aston Key also wrote of this hernia, but little or no advance was subsequently *made until* the appearance in 1865 of an important monograph by Bourguet of Aix Other writers have added one or more cases occurring under their observation Among these are Berger, Monod, and Terillon Montazm, D'Arcy Power, Heaton, and Scloke There can, I take it, be little doubt that there has been considerable confusion in the description of cases as being "encysted" Many cases of hernia in association with hydrocele of the tunica vaginalis have been included under a misapprehension as to the authentic meaning of the term "encysted" *Cases of* hernia with a cystic condition of the wall of the sac possibly due to the organ of Giraldès and cases in which adhesions and fluid are present in the sac have been similarly misunderstood Until Lockwood carefully defined and restricted the term "infantile," many ruptures *of this form* were certainly looked upon as "encysted," and to some extent the error still persists

DESCRIPTION OF THE VARIOUS FORMS OF "ENCYSTED HERNIA"

I propose to describe three *forms of encysted* hernia · (1) encysted hernia of the tunica vaginalis, the testis lying at the bottom of the cavity (Fig 8 B), (2) encysted hernia of the tunica vaginalis, the testis lying at the lower end, and "apex" of the encysted mass (Fig 8 A), and (3) encysted hernia of the funicular process (Fig 8 C)

1 *Encysted hernia of the tunica vaginalis the testis lying at the bottom of the sac* —In this case the conditions presented on examination of the sac and tunica vaginalis are as follows —On opening what appears to be the sac a little fluid as a rule escapes On enlarging the incision it is seen that the sac has not been opened, but instead a serous cavity at the bottom of which lies the testis This is the tunica vaginalis Pendent from the neck of the tunica vaginalis, which extends almost or quite up to the internal abdominal ring, is a thick, rounded elongated mass, covered on the outer side by a reflexion of the tunica vaginalis, which is the hernial sac,

FIG 8

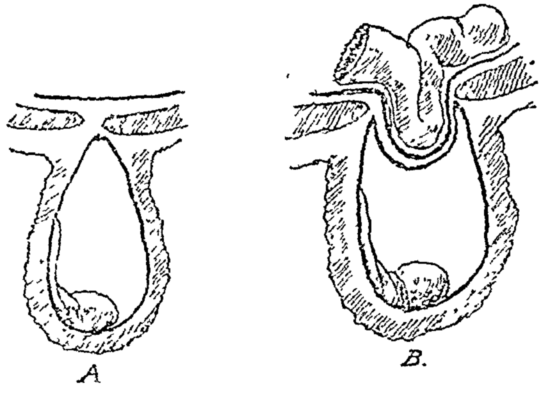


Encysted hernia.

containing the intestine, omentum, or other viscera. This pendent mass has been quite aptly compared by Bourguet to the "teat of a cow." In order to reach the hernial contents, therefore, from any point three layers of peritoneum will have to be divided, (*a*) the outer layer of the tunica vaginalis; (*b*) the inner, reflected layer of the tunica vaginalis; and (*c*) the sac. Between (*b*) and (*c*) there is some loose cellular tissue which is torn through with comparative ease. On passing the finger in through the original incision in the tunica vaginalis and attempting to enter the abdomen through the inguinal canal one is met everywhere by the reflexion of the outer on to the inner layer of the tunica vaginalis. Examples of this form of hernia, occurring in women, have been recorded by Berger and Reclus

The explanations which have been offered to account for the genesis of this condition are legion. They may be briefly epitomised thus: (*a*) Sir A. Cooper after describing Forster's case remarks: "The idea which I have formed of the nature of this case is that the tunica vaginalis, after the descent of the testis, became closed opposite the abdominal ring, but remained open above and below it. That the intestine descended into the upper part and elongated both the adhesion and the tunica vaginalis so as to form it into a bag which descended into the tunica vaginalis below the adhesion and becoming narrow at its neck though wide at its fundus, it received a portion of intestine which was too large either to be returned into the abdomen or to retain its functions while it continued in the sac." The disadvantages of this theory have been pointed out by many subsequent writers. There is never, so far as we know, any evidence in the closure of the funicular process of the formation of a "septum." The process of closure is similar in all its details to that which in the peritoneal cavity of the embryo is normal in certain points, the process of "physiological fusion." Notwithstanding this fact Berger has, on wholly insufficient evidence, accepted this explanation as elucidating the conditions in a case recently observed by him. (*b*) Dupuytren considered that the formation of a large congenital hydrocele was an essential preliminary. Subsequently to this a hernia developed and lay posterior to the hydrocele sac. Then owing to mutual encroachment the hernial sac became embedded in and surrounded by the hydrocele until in the final event the "encysting" resulted. (*c*) Jaboulay offered an ingenious but, as I believe, incorrect theory to account for the condition. He suggests that the funicular process consists of three parts—a scrotal, an inguinal lying in the canal, and an internal (very short) joining the latter to the parietal peritoneum—which may be likened to the three tubes of a telescope. By the "shutting up" of these tubes the conditions present in encysted hernia are reproduced. This explanation is rendered clearer by a reference to the figures which he gives. (*d*) The explanation which appears to me to be the most satisfactory was, I recently learnt, first suggested by Bourguet in his original work. According to this theory the closure of the funicular process has only occurred at one spot at or near the internal abdominal ring (Fig. 9). From here to the bottom of the scrotum the peritoneal tube remains open. A hernial sac now forms in the usual manner from the parietal peritoneum, at the internal abdominal ring, originated possibly by a small dimple of the upper part of the funicular process above the sole point of closure. This hernial sac as it gradually insinuates its way through the canal and into the scrotum pushes before it the peritoneum of the unclosed funicular process, and invaginates its upper end. The "fusion" point of the funicular process will then form the tip of the advancing hernial mass, which is therefore from its earliest beginnings "encysted." In three cases of this kind recorded by Dupuytren, Bourguet, and Berger, a rupture has occurred at the "apex" of the sac and the bowel, escaping into the tunica vaginalis, has been strangled at the point of rupture. Barret de Navaris has recorded an example of hernia encysted in a hæmatocele of the tunica vaginalis.

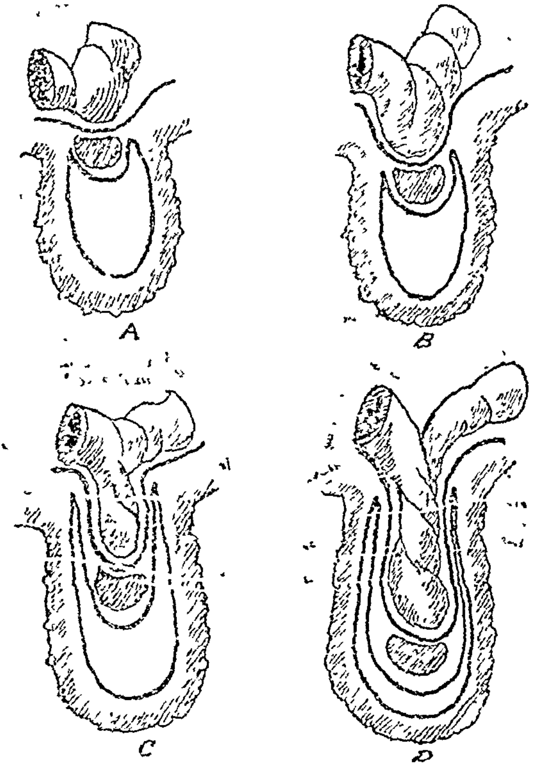
FIG. 9.



Formation of encysted hernia (first variety).

2. *Encysted hernia of the tunica vaginalis, the testis lying at the lower end, the "apex" of the encysted mass.*—The conditions found on examination of this class of hernia are precisely the same as those in the last class, with the exception that the testis, instead of lying on the floor of the tunica vaginalis, lies on the apex of the encysted tumour at the orifice, so to speak, of the "teat." The elements of the cord and the testis lie between the sac and the reflected layer of the tunica vaginalis. An essential preliminary to this form of hernia is the retention of the testis (Fig. 10).

FIG. 10.



Formation of encysted hernia (second variety).

This has been observed and carefully noted in some of the cases. In Heaton's case and in my own the testis had never to the patient's knowledge appeared at the external ring The condition antecedent to the onset of the hernia will be this. The testis will be retained just outside the peritoneal cavity. The upper part of the funicular process is closed in the usual manner, so that above the testis is the peritoneal cavity completely shut off, and below it, and reaching up to it, the lower unclosed part of the funicular process. A protrusion of parietal peritoneum from the internal abdominal ring abuts immediately upon the testis, and in the further hernial descent the protrusion is headed by that organ. But as the testis proceeds it at once meets the tunica vaginalis; this it dimples and pushes in upon itself, and in the last stage the similar serous reduplication is produced as in the former case. So far as I am aware this form of hernia, although described, has never been explained. The explanation which I suggest seems reasonable and in consonance with all the facts.

3. *Encysted hernia of the funicular process.*—In this form of hernia the sac is formed in the same way as in the first variety, but the closure of the funicular process has been more extensive. The normal fusion at the upper end of the tunica vaginalis has resulted in the natural formation of that serous cavity. The funicular process above that point of fusion has remained open and it is into this potential "hydrocele of the cord" that the hernial sac descends and becomes encysted. A very good example of this form is recorded and figured by Selcke. In one recorded case where the condition was in an early stage of its development there were two small hydroceles of the cord between the sac and the tunica vaginalis. As a general rule it has been specially noted by the recorders of the few genuine cases that hydrocele fluid of greater or less amount has been present in the enveloping serous sac, but this fluid is merely a chance product It stands in no causal relation to the hernial development.

SYMPTOMS.

There is no symptom, there are no signs, by which we can before operation recognise the presence of an encysted hernia. On the contrary, when any diagnosis other than that of a normal oblique inguinal hernia has been made it has indicated only the existence of fluid in connexion with the sac. In not a few cases this has been observed and a diagnosis of "hernia with hydrocele" has been accepted.

TREATMENT.

There is no need for any further remark than this, that in removing the tunica vaginalis, or part of it, and the hernial sac care must be exercised in dealing with the cord, otherwise the spermatic vessels or the vas deferens may be unduly interfered with. The whole of the tunica vaginalis, so far as possible, must be removed. It is not necessary to fashion a new and smaller serous cavity for the testicle. When this procedure has been carried out it has led to the occurrence of hydrocele.

ASSISTANT SURGEON TO THE ROYAL LONDON OPHTHALMIC HOSPITAL.

LECTURE III.[1]

Delivered on Feb. 16th.

ELASTIC TISSUE OF THE HUMAN SCLEROTIC.

MR. VICE-PRESIDENT AND GENTLEMEN,—The human sclerotic, consisting chiefly of white fibrous tissue, contains also a number of delicate yellow elastic fibres. The distribution of these is well shown in sections stained with acid orcein by which they are picked out a bright red. They may be seen cut transversely when they appear as little dots, and longitudinally when for the most part they run parallel with the bundles of white fibrous tissue and have a wavy course. The outer layers of the sclerotic contain more elastic fibres than the inner, and they are more numerous posteriorly than anteriorly. Around the entrance of the optic nerve there is quite a dense plexus of them. The lamina cribrosa is largely composed of elastic fibres which extend across the nerve fibres from the plexus in the sclerotic on each side. From the lamina cribrosa a delicate network of elastic fibres extends backwards around the central blood-vessels of the optic nerve. In both the pial and the dural sheaths of the optic nerve there are numerous elastic fibres. In the former they are like those in the sclerotic, fine and delicate, but they run a more tortuous course. In the dural sheath the elastic fibres are thicker than are those in the sclerotic, but they have the same wavy character, and they run parallel to the bundles of white fibrous tissue. In the tendons of the recti muscles, where they are inserted into the sclerotic, thick elastic fibres are deeply stained by the acid orcein; they are especially numerous in the sheath around the muscles. This arrangement of the elastic fibres in the sclerotic which I have described corresponds very closely to that which was demonstrated by Professor Salter at the twenty-fifth Ophthalmological Congress at Heidelberg in 1896, who employed what he terms Spaltenholz's method of staining which he says shows up the elastic fibres black against a yellow background.

STRUCTURE OF THE SCLEROTIC IN DIFFERENT ANIMALS.

The structure of the sclerotic presents several variations in the different species of the animal kingdom. In elasmobranch fish it consists of hyaline cartilage from the sclero-corneal margin right back to the optic nerve with only a small amount of fibrous tissue on its outer surface. In most teleostean fish there is hyaline cartilage anteriorly extending up to the margin of the cornea, but posteriorly there is only fibrous tissue, or fibrous tissue with scattered patches of cartilage in it. In birds and in some reptiles there is a cup of hyaline cartilage posteriorly extending forwards beyond the level of the ora serrata and anterior to it are plates of bone. In other reptiles the sclerotic is fibrous throughout. In all mammals, with the exception of the ornithorrhynchus and the echidna, the sclerotic is entirely fibrous. In the two exceptional mammals it contains a cup-shaped piece of hyaline cartilage at the posterior part extending forwards as far as the ora serrata and having fibrous tissue on its inner and outer surfaces.

HYALINE CARTILAGE IN THE SCLEROTIC OF CONGENITALLY MALFORMED HUMAN EYES.

In some congenitally microphthalmic human eyes which have presented several malformations and had cystic protrusions connected with them pieces of hyaline cartilage have been found in the fibrous tissue of the sclerotic. I have met with one such case myself. The eye was removed from a child aged 14 weeks, and was noted to have been defective since birth. The cornea and the whole globe were exceedingly small. Attached to its lower part in front of the optic nerve was a thin-walled lobulated cyst lined with retinal tissue. At the upper part of the globe, lying in front of a large portion of the cornea, partly embedded in it and partly in the sclerotic, was a broad plate of hyaline cartilage which ended anteriorly in a rounded extremity amongst the fibrous tissues beneath the epithelium of the conjunctiva. Posteriorly it also ended in a rounded extremity surrounded by fibrous tissue and projected as a sort of spur from the sclerotic about the equator of the globe, there being fatty tissue in the recess left between the spur and the sclerotic. There was a second piece of hyaline cartilage in the sclerotic on the opposite side of the globe which commenced posteriorly in a rounded extremity a short distance from the optic nerve and the anterior termination of which was not shown in my sections. In some sections this last piece of cartilage was seen as a circular patch lying in the fibrous tissue between the eyeball and the cyst.

Mitvalski,[2] in the description of a somewhat similar microphthalmic eye with a cystic protrusion, says: "Where the scleral tissue passes over into the fibrous wall of the sac there is on each side in the entire length of the ball a mass of cartilage" Dr. Lapersonne[3] also mentions and figures a piece of hyaline cartilage embedded in fibrous tissue lying between a microphthalmic eyeball and a cystic formation connected with it.

VARIOUS FORMS OF CYSTOID AND BULGING SCARS MET WITH AFTER OPERATIONS.

The peculiar bulging translucent form of scar which is met with sometimes after operations on the eye, most frequently after iridectomy for glaucoma, was first described by von Graefe and termed by him "cystoid cicatrix." I have previously demonstrated how microscopical examination of such cicatrices shows them to consist of a gap in the sclero-corneal tissue covere[illegible]iva and lined by a piece of atrophied iris.[illegible] produced by the prolapse of a fold of iris does not, from their clinical appearances alone, appear obvious and has been doubted. Pathological examination of a large number of cicatrices has, however, convinced me that for a permanent fistula to become established in the fibrous tissue tunic of the globe it is necessary that the two edges of the wound should become lined by cells of an epithelial character, otherwise plastic exudation is sure to be thrown out and to lead to their union. When a fold of iris becomes incarcerated this epithelial lining is supplied by the pigment epithelium on its posterior surface. I have found in some cases the lining also in part furnished by the most anterior of the ciliary processes and a turning forward of one of the divided ends of Descemet's membrane with its endothelial cells. I have had recently to examine a glaucomatous eye in which a short time previously to excision the operation for incision of the iritic angle, in the way suggested by Valude, had been performed. It is interesting in two ways. First, it shows how difficult it is to know when the point of the knife is passed into the iritic angle, for though the operator, a most experienced ophthalmic surgeon, aimed at the angle of the chamber, sections of the eye show that the sclero-corneal tissue some distance inside of it was incised. Secondly, it shows that a wound in the sclero-corneal tissue at the periphery of the anterior chamber in a glaucomatous eye will, unless it has an epithelial lining, soon heal up, and not remain as a permanent fistula. In this eye the aqueous humour escaped beneath the conjunctiva at the time of the operation, but in the specimen the outer layers of the sclero-corneal tissue have already become united, with round-celled exudation between them.

[2] Archives of O[illegible]

[3] Archives [illegible]

Von Graefe pointed out that cystoid cicatrices are not met with in the cornea and we can easily understand how this is due to its not being covered by conjunctiva. A permanent gap established in it would lead to a leaking fistula. Cystoid cicatrices are rarely, if ever, met with anywhere but within a few millimetres of the sclero-corneal margin—i.e., they are rarely if ever met with anywhere except in the region in which prolapses of folds of iris are likely to occur. It is the loose and mobile character of the iris which allows of a piece of it so readily protruding into a wound. The more firmly fixed and stretched arrangement of the other portions of the uveal tract, the ciliary body and choroid, tends to prevent folds of them becoming entangled.

The pathological examination of eyes upon which operations have been performed has shown me that there are three conditions, presenting somewhat different clinical appearances, which result from entanglements of folds of iris in a scar. More than one of these conditions may be present in the course of the same cicatrix. First, there is the typical translucent cystoid cicatrix, the condition which is essential for its formation being the protrusion of a fold of iris through the whole thickness of the sclero-corneal tissue, so that there is nothing but conjunctiva external to its most prominent part. A tendency to increase of tension after healing of the wound favours its development, for when the tension is increased, the gap, which is a weak spot in the walls of the globe, more quickly stretches, the iris lining it consequently becoming more rapidly atrophied and permeable by the aqueous humour. (After a cystoid cicatrix is once established the tension is often found slightly minus, due to the ready escape of the aqueous humour through it into the sub-conjunctival tissue.) The smaller the fold of iris entangled, provided it is sufficient to line completely both edges of the sclero-corneal wound, the more readily will the cystoid condition develop, for then there is less iris tissue to become stretched out and atrophied. Thus the condition is often met with after iridectomy, when a portion of the root only of the iris is left to become entangled as a fold in the wound.

The second condition which results from the incarceration of a fold of iris is what would be termed clinically a bulging scar. In it the fold does not extend throughout the whole thickness of the sclero-corneal tissue, so that from before backwards there is conjunctiva, reunited anterior layers of sclero corneal tissue, entangled iris, and then a gap in the posterior layers of the sclero-corneal tissue. Such a spot in the walls of the eyeball would also be a weak one and, as the result of increase of tension, or even sometimes as the result of normal tension, liable to give and bulge. But owing to the presence of the reunited anterior layers of sclero-corneal tissue it does not allow of the filtration of aqueous humour through it and has not the translucent appearance of a cystoid scar.

The third condition is what might be spoken of as a staphylomatous scar, though the name does not very definitely distinguish it from the previous condition. It is met with when the whole length of the iris from its ciliary to its pupillary margin has become prolapsed as a fold into a wound at the sclero-corneal margin, so that its entire thickness is kept from reuniting. Before the whole iris becomes sufficiently atrophied to be permeable by the aqueous humour it is capable of considerable distension. Hence in this condition a large, thin-walled, greyish prominence of considerable dimensions forms in the region of the scar. This is the form of cicatrix which frequently resulted from the operation of sclerotomy as performed by the late Mr. Bader, who after completing his incision encouraged the iris to prolapse.

SUPPURATIVE PANOPHTHALMITIS IN EYES WITH CYSTOID SCARS.

The chief danger in connexion with cystoid scars is, as was pointed out by von Graefe, the liability of such eyes to become the seat of a suppurative panophthalmitis months or years after the healing of the wound. Many cases of this sort have now been recorded. The following is a typical one in which I have had the opportunity of making a pathological examination of the eyeball.

A man, aged 20 years, was admitted to the Moorfields Hospital in September, 1893. His left eye was said to have been first affected when he was two years old; he never remembered having seen much with it. He had had several operations performed, the first when he was three and a half years old. One of these had resulted in the formation of a small cystoid scar at the lower and inner part of the corneal margin. Three weeks previously to admission to the hospital, while boxing, he received a blow on the defective eye. The lids afterwards became discoloured and the eye inflamed and watery. On admission there was conjunctival and ciliary injection, haze of the cornea, an hypopyon, an opaque lens, and a coloboma of the iris down and in, in the direction of the cystoid scar. The tension was minus and the vision reduced to bare hand movement. The eye was excised and on examination, in the region of the cystoid scar, a well-marked gap in the sclero-corneal tissue was seen, lined by the root of the iris. The lens was *in situ*. There was extensive suppuration in the vitreous, most intense, and radiating from the lower and inner part of the ciliary body. Microscopically extensive round cell infiltration could be seen in the sub-epithelial tissue around the scar, and extending along the iris tissue incarcerated in it. There was also much round cell infiltration of the ciliary body and vitreous in its neighbourhood. In this case I think there can be no doubt that the infection of the eye passed through the cystoid cicatrix and was consequent upon the blow. This blow may have caused an abrasion of the epithelium over it or started an inflammation of the conjunctiva in the course of which the epithelium overlying it became softened; in either case, a route being formed for the passage of infective material into the sub-epithelial tissue of the conjunctiva it had evidently spread into the iris tissue adherent to that membrane and so through the gap in the sclero-corneal tissue to the ciliary body.

Wagenmann[‡] has collected 13 cases from Leber's clinique in which suppurative hyalitis occurred at periods varying from a few months to some years after the healing of a wound and in which a cystoid cicatrix or entanglement of iris was present. He made a microscopical examination of 11 of the eyes and in all of them found micro-organisms. He considers that the history and anatomical appearances in these cases is in favour of a new infection of the cicatrix from without rather than that the micrococci entered the wound before it healed and had then for a long time remained inert, or that they had been brought to the cicatrix by the circulation and found there a congenial soil.

SEROUS AND PLASTIC INFLAMMATION IN EYES WITH CYSTOID SCARS OR SUB-CONJUNCTIVAL ENTANGLEMENTS OF IRIS.

It seems, then, that there is good evidence that the infection which gives rise to a suppurative inflammation may find its way into the interior of the eye along the track of a piece of sub-conjunctivally prolapsed iris some considerable time after a wound has healed. It would be very probable, therefore, that the infection which gives rise to less severe forms of inflammation, of a serous or plastic type, might gain access to the interior of the eye in a similar manner.

[‡] Archiv für Ophthalmologie, 1889, Band xxxv., Abtheilung 4, S. 115.

The following is the brief epitome of a case, which I have elsewhere recorded in full, in which this is what seems to have occurred.

A lady had an iridectomy performed for chronic glaucoma; this was followed by relief of tension and the formation of a cystoid cicatrix. A year later when out driving she caught cold in the eye, after which iritis ensued with the formation of posterior synechia. The eye was excised for the relief of pain and microscopical examination showed the atrophied root of the iris and anterior part of the ciliary body lining the cystoid scar.

The next case which I wish to bring to your notice is that of a woman, aged 55 years, who was struck on her right eye by a fist and who attended as an out-patient three days later, when it was found that there had been a rupture of the sclerotic extending round and concentric with the upper half of the cornea, but without any lesion that could be detected of the conjunctiva. The iris was drawn up into the rupture so as to simulate a coloboma. 24 days later she again attended the hospital with circum-corneal injection in the left eye, iritis, and numerous posterior synechiæ. She stated that 18 days after the injury she first noticed a dimness of sight in that eye. The right eye, which was at that time also much inflamed, was then excised. The left eye, in spite of treatment, ultimately became quite blind. Microscopical examination of sections at the seat of the rupture in the right eye showed the epithelium of the conjunctiva forming an unbroken layer, and in the tissue immediately beneath it and superficial to the sclerotic much round celled infiltration. The iris was folded in two in the middle and drawn into the fibrous tissue at the seat of the rupture. In this position it was much thickened with infiltration of small round cells, as also was the ciliary body and choroid in the interior of the eye.

In this case infection evidently found its way into the sub-epithelial tissue of the conjunctiva and caused cell exudation there, though no apparent lesion of it was discovered. The iris lying in contact with the sub-conjunctival tissue next became affected, and along it through the line of the rupture in the sclerotic infection spread to other portions of the uveal tract in the interior of the globe, exciting in them a plastic inflammation. The plastic inflammation thus started, like plastic inflammation of the uveal tracts started by penetrating wounds of the eye, was capable of exciting inflammation of a similar character in its fellow eye—that is, sympathetic ophthalmitis. Other cases similar to this have been recorded; Schirmer collected several, in some of which the evidence as to absence of any lesion of the conjunctiva seemed undoubted.

HOW SYMPATHETIC OPHTHALMITIS MAY ARISE MONTHS OR YEARS AFTER THE RECEIPT OF AN INJURY.

The possibility of infection which gives rise to a serous or plastic inflammation finding its way into the interior of the eye from the sub conjunctival tissue along the track of a piece of prolapsed iris offers, I think, a possible explanation of the way in which sympathetic ophthalmitis may be set up months or years after the receipt of a wound to the exciting eye. In such cases it is usual, previously to the onset of the sympathetic disease, for some fresh attack of inflammation or irritability to have been noted in the exciting eye. Indeed, a committee of the Ophthalmological Society of the United Kingdom after much collective investigation could only find nine undoubted cases of sympathetic ophthalmitis arising after a long interval in which such an attack was not noted in the exciting eye, though they describe those in which it was present as fairly numerous. The fresh attack of inflammation or irritability in these cases is probably the starting-pointing of fresh infection of the exciting eye from without. Any eye with a sub-conjunctival entanglement of the uveal tract is probably liable, as the result of some conjunctivitis in which infective material enters the sub-epithelial tissue, to become the starting-point of sympathetic disease, no matter how long a time may have elapsed from the receipt of the original injury.

HOW SYMPATHETIC OPHTHALMITIS MAY ARISE AFTER THE OPERATION OF ABSCISSION.

Eyes which if left to themselves were not likely to have started sympathetic inflammation have sometimes had the operation of abscission performed on them, and then, after complete recovery from the operation, as the result of some fresh irritation, such as that caused by the wearing of an artificial eye, have become the exciting cause of an attack of sympathetic ophthalmitis. The way in which such a course of events may be brought about is, I think, suggested by the following case.

An eye was wounded by a nail and the same day the operation of abscission was performed. Two and a half years later the stump of the eye which was left, having become irritable and painful, was excised. Pathological examination of it showed that at the abscission operation the sclera had been divided close to the corneal margin; on one side nearly all of the ciliary muscle had been left, whilst on the opposite side it had in great part been removed. The retina was detached from the choroid but remained adherent at the optic disc; some remnants of degenerated vitreous were contained between its folds. The lens was absent. Microscopical examination of the cicatrix where the two edges of the sclerotic had been brought together showed a piece of the anterior portion of the ciliary body incarcerated in it. Beneath the epithelium in the sub-conjunctival tissue overlying the cicatrix was some round cell infiltration; there was also much round cell infiltration of the entangled piece of the ciliary body lying in the cicatrix. The infiltration had not, however, extended to the uveal tract within the eyeball, though it probably would have done so if the eye had been left and not enucleated. This eye might then later have excited sympathetic inflammation in its fellow. I may here remark that an entangled piece of the uveal tract may easily escape detection by clinical examination. To be sure that no entanglement is present it is necessary to examine microscopically sections taken from different portions of the whole length of a cicatrix. The above case is one in point, clinically no entanglement was noted.

A REASON WHY WOUNDS OF THE CILIARY REGION ARE SPECIALLY PRONE TO BE FOLLOWED BY SYMPATHETIC OPHTHALMITIS.

The ciliary region is the part of the eye in which sub-conjunctival prolapses of the uveal tract are most likely to occur. Behind the ciliary region the choroidal tissue but rarely prolapses through an opening in the sclerotic; it tends to retract away from the sides of the wound when divided. In wounds of the cornea entanglements of the iris may occur, but then the iris is not left with a vascular membrane lying over it prone to inflammation like the conjunctiva. The possibility of sub-conjunctival entanglements of the iris or ciliary body forming the track along which inflammation likely to excite sympathetic disease may enter an eye, any time after the receipt of an injury, may be one reason why wounds of the ciliary region are specially liable to be followed by this complication.

DECREASE IN THE AMOUNT OF SYMPATHETIC OPHTHALMITIS.

Ignorant as we still are as to the nature of the infective agent which causes sympathetic ophthalmitis and as to the course which it takes in travelling from one eye to the other, it is satisfactory to be able to show that at the Royal London Ophthalmic Hospital, Moorfields, of late years there has been a gradual decrease in the number of cases of this disease admitted for treatment. Thus, in the 15 years during which I have been connected with that institution (from 1884 to 1898) I find, dividing them into three quinquennial periods, that from 1884 to 1888 there were 97 cases of sympathetic ophthalmitis admitted, out of a total of 10,676 in-patients, or 0·9 per cent; from 1889 to 1893 there were 62 cases of sympathetic ophthalmitis admitted out of a total of 10,095 in-patients, or 0·61 per cent.; and from 1894 to 1898 there were 47 cases of sympathetic ophthalmitis admitted, out of a total of 10,366 in-patients, or 0·43 per cent. This decrease in the amount of sympathetic ophthalmitis may in part be due to more thorough aseptic and antiseptic precautions. I think, however, that it is also in part attributable to the greater care which surgeons have instinctively come to take in avoiding entanglements of the iris in their operations, and in clearing accidentally inflicted wounds as much as possible of any incarcerated portions of the uveal tract.

DANGERS RESULTING FROM THE PROLAPSE OF TAGS OF VITREOUS HUMOUR.

I have now to bring before you a specimen which exhibits another, probably not infrequent, way in which infective inflammation may gain entrance to a wounded eye, but in which the necessary conditions will not exist for any great length of time after the infliction of a wound.

A woman, aged 61 years, who had suffered from glaucoma in her left eye for four years, which had rendered it quite blind, with the hope of relieving pain had a puncture of the sclerotic performed with a Graefe's knife about the equator of the globe to the inner side of the superior rectus muscle. Ten days later the eye, being still very painful and the tension much raised, was excised. Pathological examination showed thickening and abnormal adhesion of tissue to the sclerotic between the superior and internal rectus muscles and just behind the line of their insertion. Yellow streaks were seen in the vitreous radiating from this position, where it was abnormally adherent to the retina. Microscopically, in the region of the incision a gap was seen in all three tunics of the globe passing through the anterior part of the choroid, the edges of which had become somewhat retracted, and through the retina just behind the ora serrata. Lying in the gap and protruding a little way on the external surface of the globe was a portion of the vitreous humour much infiltrated with small round cells and continuous with the rest of the vitreous in the eye, which in the neighbourhood of the wound and radiating from it was similarly infiltrated, as also were the divided edges of the retina and choroid.

There can, I think, be no doubt that in this case the prolapse of tag of the vitreous humour formed a channel along which inflammatory infection was able to travel into the interior of the eyeball. The possibility of infection gaining entrance from the conjunctival sac in this manner through a scleral puncture intentionally made can generally be guarded against by first displacing the conjunctiva in the position at which the operation is to be performed, so that when it is completed the openings in the conjunctiva and the sclera do not correspond. It shows also the importance of drawing together the edges of a scleral wound accidentally inflicted with superficial sutures.

Another surgical operation in which prolapses of tags of vitreous humour are sometimes met with is that of needling a membrane after extraction of cataract. Pieces of vitreous humour which follow the needle on its withdrawal may for days afterwards be seen as filamentous processes on the surface of the cornea. I have several times seen eyes in which such a complication has occurred become the seat of troublesome inflammation. I may add that since adopting the method of introducing the needle through the sclero-corneal margin instead of through the cornea for the discission of a membrane I have not had any prolapses of this nature.

Microscopical Appearances of Different Forms of Membranes left after Extraction of Cataracts.

The various conditions seen microscopically in membranes left after the extraction of cataracts are of considerable practical as well as pathological interest. The hyaline lens capsule left after removal of a cataract usually appears thicker than it does in the normal condition. This thickening is not due to any addition to its substance, for it is observed in eyes in which too short a time has elapsed since the removal of the lens to allow of any new growth. It is, I think, accounted for by the elastic character of the membrane, which is on the stretch and elongated when it surrounds the lens, but after its removal becomes shortened and thickened. Though there is a certain amount of shortening, it is not usually sufficient to allow of the anterior part of the capsule lying smoothly in contact with the posterior part over any large area. The anterior part is generally thrown into several folds. These folds by themselves must tend to break up rays of light and to cause some defect in vision; they are, however, nearly always associated with one of the other conditions to be mentioned directly. The microscopical examination of opaque membranes after the extraction of cataracts shows that they may be classified under the following headings: (1) retained lens substance; (2) new growth of capsule cells; and (3) adventitious fibrous tissue.

1. After the extraction of a cataract any lens substance which is left is at first exposed through the opening made in the capsule to the action of the aqueous humour, but later the opening becomes sealed up by the proliferation of the capsule cells at its margins; any lens substance thus locked up, which if not originally opaque will have become so, is shut off from the dissolving fluid. A lens, unless extracted in its capsule, is hardly ever removed so completely that some of its peripheral portions are not left which become closed up in this way. It is, of course, only when portions of lens substance are retained in the pupillary area that they give rise to any disturbance of vision, and opacity due to it is seen directly after extraction or within a few days of the operation. Lens substance retained in this way for several years will sometimes have calcareous matter deposited in it.

2. The epithelial cells lining the capsule in the region of the nucleated zone, when left after the extraction of a cataract, tend to proliferate, shift round, and then become separated from the capsule, as they do when the lens is intact. They do not, however, as they afterwards enlarge, become flattened out into lens fibres, but form large vesicular cells, sometimes oval, sometimes circular, in shape, this alteration being due to the lessened amount of pressure to which they are exposed. The cells lining the more central portions of the capsule sometimes, also, multiply and develop into the same swollen, bladder-like cells, the capsule then being raised into prominences over little groups of them. A more frequent result, however, of the proliferation of the cells lining the more central portions of the anterior capsule is the lengthening of them out into spindle shapes and into delicate fibres, which form a dense laminated tissue. It is with this sort of tissue that the opening left in the capsule after the removal of a cataract becomes sealed up, and with this sort of tissue the spaces left by the rucking of the anterior capsule most frequently become filled. This tissue exactly resembles that which is met with in anterior polar opacities, which is produced in a similar way, and like it varies in its density according to the time which has elapsed since its formation. Occasionally when it has been in existence for a long time hyaline bands are met with between the laminæ. It is the formation of this sort of tissue which gives rise to the opacity causing deterioration of vision coming on some time after the extraction of a cataract, and the longer it has existed the more fibrous, dense, and tough does it tend to become; consequently the more difficult to cut or tear with a needle.

3. Adventitious fibrous tissue may form as the result of cell exudation in iritis on the front of the anterior capsule after extraction or behind the posterior capsule about the hyaloid of the vitreous as the result of cyclitis. Sometimes a blood clot on the anterior capsule will form a sort of matrix in which fibrous tissue will develop.

In severe cases of iridocyclitis the anterior and posterior capsule may become embedded in fibrous tissue, forming a dense partition between the aqueous and vitreous chambers. It is the contraction of adventitious fibrous tissue on the surface of the anterior capsule, united to the extraction scar, that gives rise to an updrawn pupil after the removal of a cataract. I have examined microscopically an eye in which at the operation for the extraction of a cataract an opening in the lens capsule was made by grasping and tearing a piece of it away with forceps and which eleven years later was excised on account of detachment of the retina, which was thought possibly might be due to a new growth. The sections showed that about two-thirds of what may be spoken of as the anterior capsule with its lining epithelium had been removed opposite the pupillary area the posterior capsule without any lining cells alone being left. It is obvious that if a portion of the anterior capsule is removed in this way any cortical lens substance which is left cannot in the region from which the piece has been torn become re-enclosed away from the action of the dissolving aqueous humour; so that any opacity occurring after the removal of a cataract due to opaque cortical substance in which capsulotomy was thus performed would only be of temporary duration. Further, no opacity could form in the region from which the piece had been removed due to the proliferation of the cells lining the anterior capsule. Occasionally in cataractous lenses cells are met with lining the posterior capsule where normally they are absent. If these were present they would be left both when the capsule is opened with forceps and with the cystotome. Whether if left freely exposed to the aqueous humour they would be capable of proliferating and causing some opacity I am unable to say, but seeing that lens fibres, which normally develop from them, are dissolved by the aqueous humour I think it is improbable. The removal of a piece of the anterior capsule opposite the pupillary area with forceps would seem, therefore, to be a procedure likely to obviate two of the causes known to give rise to secondary opacities.

RADIOGRAPHIC RESEARCHES ON THE

TOPOGRAPHICAL RELATIONS OF THE BRAIN, THE FRONTAL AND MAXILLARY SINUSES, AND THE VENOUS SINUSES OF THE DURA MATER TO THE WALLS OF THE SKULL.

BY DR. PAUL REGNIER,
PROFESSEUR AGRÉGÉ, SURGEON TO THE HÔPITAL LARIBOISIÈRE;

AND

DR. JULES GLOVER,
ANCIEN INTERNE DE LA CLINIQUE OTO-LARYNGOLOGIQUE DE L'HÔPITAL LARIBOISIÈRE.

(*Translated for* THE LANCET.)

THE present paper is an account of a research undertaken by us in which radiographic methods were applied to the investigation of the anatomy of the skull and the face. The observations were made in the Radiographic Laboratory at the Ecole Pratique of the Faculty of Medicine of Paris. 14 radiographs, together with our memoir, were submitted to the Paris Academy of Medicine at the meeting held on August 10th, 1897. Reproductions of three of our radiographs will be found in the *Journal des Praticiens* of Sept. 4th, 1897, and also in *La Radiographie*. The investigations led us to the following results:—

1. Regarded in its surgical aspect the topography of the skull and brain may be studied by radiographic methods, allowance being made for the fact that the views which are obtained by the processes in question inevitably present some very slight distortions. By means of radiography it is possible to see the brain through the skull. More than that, an important guide-mark in the study of the topographical anatomy of the brain and skull is furnished by the circumstance that in the photographic plate it appears to be possible to superpose the outline of the cranial sutures on the outline of the fissures which separate the cerebral convolutions from one another By these methods the relations between the cerebral convolutions and the walls of the skull, so interesting from the point of view of surgical intervention, can be studied with almost no preliminary preparation which might have the effect of materially modifying the exact relations between the brain and the skull. Similarly we may point out that on the radiograph of the cerebral convolutions, viewed through their bony covering, the outlines and the form of the lateral ventricle of the cerebral hemisphere are very exactly traced.

2. The immediate relations existing between the venous sinuses of the dura mater and the skull, and in particular those existing between the lateral sinus and the skull, may be defined both in the child and in the adult. Injections of the venous sinuses of the dura mater made with liquids which ultimately become solid, and which hold metallic substances in suspension, as well as some other devices to the same end, have enabled us to see these sinuses very clearly through the bony wall Our radiographs show the lateral sinus, as our researches were particularly directed to this important point of surgical anatomy.

3. We have also been able to study, especially in dried preparations, the extremely variable extent and form of the cavities and bony cells of the mastoid process, as well as of the maxillary, frontal, and sphenoidal sinuses, and of the ethmoidal cells.

4. It has been possible for us to recognise in the infant and in the adult the exact position with reference to the outside of the skull occupied by the petrous portion of the temporal bone and the three successive levels of the base of the skull. We have easily obtained, in specimens covered with their soft parts, the opaque triangular outline of the base of implantation of the petrous portion on the squamous portion of the temporal bone, as well as the outline of the three successive levels of the base in their exact relation to the external wall of the skull.

MODE OF PREPARATION OF THE SPECIMENS AND METHOD OF PROCEDURE

For our anatomical preparations we used sections of the head through the middle line with the view of proportionately diminishing the number of bony surfaces, of which there would be too many if the entire thickness of the head had to be traversed by the cathodic rays. One must be careful to select young subjects in whom the cranial sutures are not yet ankylosed. Before making the section of the head in the vertical and antero-posterior directions the specimen was injected with formol introduced by the carotid artery. This arterial injection was repeated two or three times at intervals of one or two days with the object of hardening the brain without appreciably changing its shape or size. The soft parts covering the skull and face were carefully removed and the antero-posterior section of the specimen was not made until after the lapse of a period of three weeks. The cerebral hemisphere, hardened *in situ*, was then carefully removed from the skull, freed from its pia mater, and replaced in its former position in the skull. These manipulations cannot alter the mutual relations of the brain and the skull provided that they are kept within the narrowest possible limits. On this account we abandoned the idea of making casts of the brain, for in them the conformation of the part is more liable to become altered, even when it has been hardened by formol or some other dehydrating agent. The brain must be freed from the pia mater if we wish to have the convolutions visible on the photographic plate, for when it is covered by the meninges the representation of it is less sharp. Moreover, it is advantageous by a vertical section to get rid of the convolutions of the internal aspect of the cerebral hemisphere, if one wishes to avoid having on the plate any confusion between the convolutions of the internal aspect and those of the outer surface of the hemisphere. The injections of the venous sinuses were made with bronze powder held in suspension either in a solution of wax in alcohol or else in tallow. A still better result is obtained if the course of the sinuses is indicated on the specimen by means of small metallic points—pins, for example—which come out deep black on the plate. Our radiographs of the dried skull of the adult and infant deserved particular attention, for in them the extent and the conformation of the bony cells were very plainly to be seen, both at the level of the mastoid process and at the level of the bony sinuses of the face. Our various radiographs were taken with Colardeau-Chabaud cylindrical focus tubes. The distance from the tubes to the sensitive plate was always 45 centimetres (18 inches), a distance which enabled us to obtain sharp pictures. The length of the exposure varied according to the state of the vacuum of the tube, from a few minutes to 10 and 40 minutes.

INFERENCES AND APPLICATIONS OF OUR RESEARCHES TO THE METHODICAL STUDY OF THE SURGICAL *ANATOMY OF THE BRAIN* AND SKULL.

The superficial situation of the venous sinuses of the dura mater, of the cells of the mastoid process, and of the frontal and maxillary sinuses, and their definite relations to the external surface of the skull, which give easy access to them in a host of surgical interventions, are sufficient to show, on the one hand, the ease with which it was possible to obtain the results at which we have arrived, and, on the other hand, the practical importance which these results seem to us to possess. If a certain number of radiographs of different anatomical specimens are taken, as they were by us, and if they are compared with one another, it is easy to appreciate all the anomalies and variations of the size and shape of the frontal and maxillary sinuses, and this comparison, being made with photographs, is much more exact than the method ordinarily followed in anatomical treatises—namely, the comparison of drawings of a *series* of sections cutting the bones of the face in all directions. In many of our preparations the lateral (venous) sinus formed a part of the mastoid process, a fact which was recognised long ago but which had not been so clearly demonstrated without resorting to special methods of preparation. In some specimens it corresponded to the anterior part of the mastoid or even to its centre, or, finally, in general, to the posterior fourth of the process. Allowances have to be made for some distortions of the picture, and, this being done, when radiographs obtained from a child are compared with those obtained tate the lateral sinus is less closely connected with the nastoid process in the adult and that this important venous channel seems to lie at a progressively greater distance from the bony process in proportion as the age of the subject advances from infancy upwards. At the level of the mastoid process not only are the cells of the body and of the tip very clearly recognisable according as the bony tissues contain air or are dense in their texture, but one can also easily make out certain mastoid cells which often extend backwards and downwards into the diploë between the two tables of the occipital bone. One sees also cells of still greater interest from a surgical point of view which occupy a surface of considerable extent immediately above the external auditory meatus. Moreover, if the tip of the petrous bone be removed from the preparation by a section passing internal to the tympanic cavity it will be easy to see the antrum and the tympanic cavity. In some radiographs the petrous bone is, in fact, so transparent that the orifice of the internal auditory meatus can be seen. It is unnecessary to refer in detail to the anatomical and surgical interest attaching to these results, which we were the first to obtain by utilising the transparency of the petrous bone under radiographic examination. The question is one of special importance at the present time, when so much attention is being bestowed on the operative details of the combined trephining of the mastoid process and the tympanic cavity in complicated suppurative otitis media.

With reference to the views of the cerebral convolutions obtained through the bones of the skull it may be said that a minimum distortion of the image can be reckoned on when care is taken to have the incidence of the cathodic rays exactly vertical to the anatomical preparation and consequently to the sensitive plate; in the next place the tube ought to be at a sufficient distance (50 centimetres—i.e., 20 inches—as we have said) in order that the cone of emergent rays may present its minimum of divergence. With plates taken with these precautions (and with such plates only) the topography of the brain and skull in their various aspects can be studied in the adult and with still more facility in the child.

Notwithstanding the undeniable value of the simple method by the insertion of pins through the walls of the skull into the cerebral convolutions practised long ago by Gratiolet and Broca, who were the first to study the topography of the brain and skull, it is none the less true that it would be extremely interesting to resume these complicated investigations by the aid of the wonderful method which, as we now recognise, enables us to obtain a permanent and detailed representation of the brain, irregular in form as it is, even through the bony structures which contain it. We are convinced that our pioneer researches will be the prelude to others.

The Application of our Researches to the Clinical Exploration of the Brain and the Osseous Cavities of the Face.

On examining a child's head with the fluorescent screen it is sometimes possible to perceive a clear patch corresponding to the cavity of the lateral ventricle, especially when this cavity is dilated by more or less serous effusion in the case of sufferers from hydrocephalus or meningitis. Referring to the results obtained on the anatomical preparation by taking radiographs of the brain through the skull, a method which gives a detailed representation of this ventricular cavity, it is obvious that a radiograph taken in such a case from a living child will afford more exact information than a mere examination with the fluorescent screen would do. One of us, with M. Rémy, using the fluorescent screen, has seen in the head of a child suffering from meningitis a clear patch corresponding to the median portion of the brain. This patch exists normally in young infants, but its transparency is certainly more perceptible in the pathological state when the ventricle is dilated with fluid.

In conclusion, we will say that it is easy by mere examination with the fluorescent screen to verify the transparency and the condition as to emptiness of the frontal and maxillary sinuses, and perhaps even of the mastoid cells, with much more exactness than by making use of the ordinary electric light. Instead of employing a powerful light introduced into the mouth for the illumination of the maxillary sinuses, or applied to the upper and inner margin of the orbit for the illumination of the frontal sinuses, we recommend having recourse to cylindrical focus tubes. With this object, and in order to simplify the manipulations, the tube is fixed on a small and light stand made of ebonite, or even of wood, and the observer wears caoutchouc gloves to protect himself against shocks from the current. The tube can now be brought near to, or removed from, the patient's head until the proper distance is found without causing the patient any inconvenience or danger. In the examination of the face all the cavities become visible at the same time.

TUBERCULOUS DISEASE OF THE KIDNEY: ITS ETIOLOGY, PATHOLOGY, AND SURGICAL TREATMENT.

BY DAVID NEWMAN, M.D. GLASG.,
SURGEON TO THE ROYAL INFIRMARY, GLASGOW.

TUBERCULOUS lesions of the kidney present themselves to the surgeon in many phases. In some instances when first seen by him the disease is so advanced that little can be attempted to stay its progress or to mitigate the suffering of the patient, while in other cases the malady is still limited in extent and much may be done by early surgical intervention. Even a few years ago renal tuberculosis was looked upon as almost a certainly fatal malady, but now that new and more exact methods can be employed in detecting the disease in the early stage the surgeon is not uncommonly placed in a position to advise and to carry out operative measures with considerable hope of success.

Various attempts have been made to classify diseases of the kidney into "surgical" and "medical," but it must be admitted that any such grouping is not only arbitrary and unscientific but productive of much misunderstanding and harm. An endeavour to follow such a classification has been attempted by M. Du Pasquier and M. Brissand, who adopt even now the nomenclature in use prior to the development of renal surgery. The old term "surgical kidney" was given to all secondary purulent lesions of the organ resulting from primary septic foci in the lower urinary passages—that is to say, the word "surgical" was employed to denote that the renal lesion was secondary to a malady requiring the surgeon's aid. It pointed to the etiology of the renal lesion rather than to the circumstances of how the disease required to be treated. In illustration of this it may be observed that the French writers just referred to designate as "medical" those cases of tuberculous nephritis in which the virus has been carried to the kidney by the blood, whereas those in which infective material has extended upwards from the lower urinary tract they regard as "surgical." This classification is imperfect and unsatisfactory from all points of view. Indeed, the very cases which are included under their classification as being "medical" are those most suited for surgical treatment. Take, for example, cases of caseous nephritis where the kidney has been invaded through the blood and the virus has given rise to a localised renal tuberculosis unassociated with active disease in other organs. Those cases while included by the writers above referred to as "medical" are the very ones which give the most satisfactory results to the surgeon.

To have an intelligent view of the present position o surgery to tuberculous disease of the kidney it is necessar to study very carefully the various modes of infection an the different phases of the morbid process. From a clinic standpoint tuberculous disease may be said to manifest itse in three distinct forms—namely, (1) acute miliary tuber losis; (2) local tuberculosis or renal phthisis; and (3) chro tuberculous or caseous nephritis. All these varieties are to the presence of tubercle bacilli and to an infective pro resulting therefrom, but the channels through which virus reaches the kidney and the methods by which t infection takes place vary considerably.

The etiology of tuberculous lesions of the kidney has carefully worked out and the different avenues of inf have been ascertained. Two conditions are necessary establishment of tuberculous disease in the kidney—th sence of a suitable nidus there and the conveyance of s organisms to the part. Probably on account of its ab blood-supply the healthy kidney tissue, althoug vulnerable than other parts of the urinary tract, remarkable power of destroying organisms introduced into its substance or of eliminating them from the system. To discuss how this is brought about is beyond the scope of the present inquiry, but an important clinical fact must be here referred to—namely, that tubercle bacilli carried by the blood from distant parts may be eliminated without any morbid change in structure being produced in evidence of their sojourn in the kidney. For example, they may be found in the urine of persons suffering from tuberculous disease of bone, of the lungs, or of other organs. Their presence, therefore, in the urine is not pathognomonic of tuberculous disease of the urinary tract. Although the observation of these organisms furnish positive proof that the patient is tuberculous the precise seat of the lesion remains to be determined. In cases where the kidney eliminates these bacilli without itself becoming involved in the tuberculous process it must be assumed as an explanation either that the quantity carried to the organ at a given time is too small or that the virulence of the microbes is insufficient to overcome the normal preventive power of the renal tissue and to produce the specific pathological effect. The natural power of the renal tissue in destroying micro-organisms may be rendered less powerful by abnormalities such as malformations of the organ or by disease. Hence we find that Bright's disease, cystic degeneration, amyloid degeneration, or congenital malformations and displacements all tend to make the kidney more liable to septic and tuberculous diseases, and, as in other organs so also in the kidney, injury or hæmorrhage may be an exciting cause of tuberculosis.

In order that tubercle bacilli may grow and multiply in the kidney it is necessary that they be conveyed by the blood stream to a part where there is a favourable soil for their growth and where they are not liable to be washed away by the current of blood or the flow of urine. Hence tuberculous foci are more likely to originate in the parenchyma of the organ than in the urinary passages. It is now quite recognised that the presence of the bacillus is the most important etiological factor in the disease, but at the same time other influences are at work in determining the establishment of the malady in the kidney. Acute febrile diseases, such as enteric fever, measles, scarlet fever, pneumonia, &c., and injuries produced by blows and falls are the most important predisposing causes. Sometimes the injury may not be severe enough to cause hæmaturia, but patients so frequently blame a fall or a blow that the surgeon cannot overlook insignificant traumata as possible causes. Suppose that tuberculous bacilli are present in the blood when a blow is sustained by the kidney, then the effusion of blood, with thrombosis of capillaries and the injury to the tissues, provide the conditions required. The following cases are illustrations of renal *phthisis ab hæmoptoe*.

CASE 1. *History of a fall of 26 feet; severe pain in the left renal region; hæmaturia and effusion of blood around the left kidney; apparent complete recovery from the injury; and two and a half years afterwards the patient suffering from advanced tuberculous disease of the left kidney.*—A man, aged 30 years, was admitted to the Glasgow Royal Infirmary on May 11th, 1893. While working on the deck of a steamer he had accidentally fallen into the hold, a distance of 26 feet. He was rendered unconscious and when admitted to the hospital was suffering from severe shock. Besides other injuries he complained of severe pain in the left lumbar region and the first urine passed after admission contained a considerable quantity of blood. On examination a distinct fulness and increased resistance was made out in the left flank and over this area the percussion was dull. The patient made a slow but steady recovery and he was detained in hospital until August 17th on account of the other injuries, the kidney condition having apparently been recovered from within a fortnight. The hæmaturia disappeared ten days after admission.

The patient was again seen on Nov. 27th, 1895, two and a half years after the accident, by Dr. D. McKellar Dewar, who recommended him to come into hospital, but this he refused to do, preferring to be under the care of his private medical attendant, with whom I saw him in consultation. He said that he had remained well and had been able to follow his occupation until the end of May, 1895, when he complained for the first time of a recurrence of the pain in the left lumbar region, and although on palpation a distinct dulness could be made out no fluctuation was detected. The urine was free from any deposit, blood, or albumin, but tubercle bacilli were not looked for. In November the urine contained an abundant muco-purulent deposit, six specimens of which were examined for tubercle bacilli, and in two of these bacilli were found. From May to November the patient's general health rapidly deteriorated, his appetite was impaired, and he lost 16 lb. in weight. The evening temperature was elevated irregularly and he complained of night sweats but there was no vesical irritation. By the end of December a distinct fluid accumulation was discovered in the left kidney and the patient was advised to have a nephrotomy performed, when the kidney was found to be occupied by a typical tuberculous pyonephrosis.

CASE 2. *History of a blow causing ecchymosis in the right lumbar region; hæmaturia of five days' duration with one recurrence on the eleventh day; severe pain and some swelling in the right renal region; six months after the injury the urine became muco-purulent and bloody; symptoms and physical signs of renal phthisis.*—A woman, aged 47 years, was admitted to the Glasgow Royal Infirmary on August 2nd, 1895 On inquiry it appeared that in January the patient had fallen from "house steps" a distance of eight feet and on falling struck her "right side" against the back of a chair. The blow was received on the right lumbar region and caused considerable ecchymosis between the lower ribs and the crest of the ilium. On recovering from the immediate shock of the injury she suffered severe deep pain in the region of the kidney and the urine first passed after the accident contained blood. The hæmaturia continued for five days after the injury and recurred once only on the eleventh day. There was some swelling in the region of the kidney but how long it lasted the patient did not know. Since the fall the "side" had always felt weak, but the pain was not severe till seven weeks previously to admission. About the same time she observed the urine to be dark in colour and to contain blood together with a white deposit. On admission the patient complained of a swelling in the right lumbar region. She had always been rather spare in body and lacking in colour, but she said that of late she had fallen off considerably. A month prior to admission she experienced pain in the lumbar region whenever she moved about and at the same time the urine presented the abnormal appearance above mentioned. On examination the whole space between the liver and the crest of the ilium was dull and fluctuant and presented the characteristic features of a large pyonephrosis, but there were no sudden discharges of purulent urine at any time. The specific gravity of the urine was 1012, it was strongly alkaline, and contained a considerable quantity of pus, some blood, and crystals of oxalate of lime; tubercle bacilli were numerous. On August 17th the kidney was incised, when a large quantity of pus, urine, and tuberculous débris was evacuated and a large cavity was scraped out with a Volkmann's spoon. Later in the history of the case the lungs became involved, there being dulness and abundant moist râles at the bases of both lungs behind, but at the apices there was no evidence of consolidation.

In both of the foregoing cases it was clearly shown by the history that the patients enjoyed perfect health until the occasion of the injury, and it may be safely presumed that the traumatism was the only cause of the hæmorrhage. In cases where slight indirect violence has been followed by the appearance of blood for the first time the question may be legitimately raised as to the presence of pre existing disease, which may not up to the time of the accident have shown itself by hæmaturia, but in these cases the blows were severe and direct and of themselves sufficient to injure the kidney. The most reasonable explanation seems to be that the injury reduced the resisting power of the organ by the effusion of blood into its substance and that tubercle bacilli in the effused blood, or subsequently conveyed to the neighbourhood of the effusion, took root and multiplied, formed a centre of infection, and thus produced what may be called a renal *phthisis ab hæmoptoe*.

Again, septic inflammatory lesions of the pelvis or of the renal substance predispose to tuberculous disease.

CASE 3 *Acute tonsillitis and abscess, followed by what at first appeared to be a purulent embolic nephritis, but which ultimately became tuberculous.*—A man, aged 41 years, consulted me first in November, 1895, complaining of an acute inflammation of the right tonsil which culminated in the formation of an abscess. Three days after the abscess in the tonsil was opened and the temperature had returned to normal it suddenly rose again, and in the evening the thermometer registered 104 2° F., without any recurrence of the throat affection. The patient, however, complained of considerable discomfort and a dull aching pain in the right lumbar region, and he had during the afternoon several severe rigors. The urine was at first increased in amount, excretion rising during the first three days after the onset of the renal pain to an average of 80 ounces in 24 hours. It was acid, its specific gravity was 1008, a considerable amount of mucus was deposited on standing, and it contained a moderate amount of albumin (0 3 per cent.) and some blood, but no pus. On the fourth day the patient had six rigors and for the first time pus appeared in the urine. The quantity was large at first and deposited rapidly from the urine in which it escaped. The urine had no unpleasant odour; the reaction was acid. The patient did not complain of any vesical irritation The urine was examined on six occasions for tubercle bacilli, but none was found. Pus continued to be present in the urine for over two months, but during that time it gradually diminished in amount and at the end of February, 1896, the patient resumed his occupation and was lost sight of till July, 1898. Then he complained of marked vesical irritation, passing urine over 60 times in the 24 hours. The urine had all the characters of a tuberculous pyelitis. No operation was allowed, but when the kidney was removed post mortem it was found to contain numerous tuberculous centres.

In this case the mode of onset and the early history of the disease points to the formation of an abscess in the parenchyma of the kidney, rupturing into the pelvis and there setting up a chronic pyelitis, which at a later stage became tuberculous.

It may be well now to consider the methods of attack or the channels along which the microbes of tubercle may travel. The kidney may be invaded in four different ways:—1. By the blood stream. (*a*) The tuberculous particles may be so small as to be stopped only in the ultimate capillaries, where they give rise to numerous miliary deposits (in such instances the blood stream becomes contaminated while passing through tissues or organs foreign to the urinary apparatus); or (*b*) tuberculosis may arise from infective emboli passing into a branch of the renal artery, the tuberculous virus becoming disseminated over the area of its distribution. 2. By invasion along the lymphatics of the kidney from foci in the lower urinary tract. 3. By contagion along the lumina of the excretory ducts. 4. By spreading to the kidney from continuity with other organs. It must, however, be borne in mind that while primary infection is conveyed to the kidney by one of these channels the infective process becomes more complicated as the disease advances; indeed, the mode of extension comes to involve a combination of the processes just mentioned.

The kidneys communicate with the outer world by means of the lower urinary tract, and in some instances the blood supplying these parts may become contaminated by the tuberculous virus, but probably in the great majority of cases the blood becomes infected when passing through the vessels of the respiratory organs, the alimentary canal, or the mucous or cutaneous surfaces. Having entered the circulation the bacilli may be carried into the renal artery and may be eliminated from the kidney without any serious harm resulting. Durand Fardel has demonstrated the presence of tubercle bacilli within and around the glomeruli without their giving rise to any structural changes in the kidney recognisable by the microscope, and on several occasions I have seen tubercle bacilli in the cortex of the kidney in subjects of rapidly fatal pulmonary phthisis, while in the same cases during life I have failed to detect the specific organisms in the urine.

Infection by the blood stream.—(*a*) Obstruction of the capillaries. In acute miliary tuberculosis of the kidney the virus is conveyed by the blood-vessels and is widely disseminated, so that such cases seldom come under the cognisance of the surgeon. It may, however, be interesting to follow the changes in this acute process where the tuberculous nodules are small in size and all in about the same stage of development. The tuberculous virus being conveyed to the kidney by the blood-vessels the favourite seat of the disease is in the cortex, where the little miliary growths appear as small, semi translucent, greyish streaks surrounded by a darker zone of deeply injected renal tissue. These miliary nodules are frequently arranged in rows or they form linear streaks (see Fig. 2) following the direction of the vasa interlobularia and present an appearance which closely resembles minute hæmorrhagic infarctions. In Fig. 1 the fibrous capsule is seen to be stripped off the cortex of the kidney and the deeply injected parenchyma is exposed, showing the numerous miliary tubercles as clear white pearly specks embedded in a chocolate-coloured background. In the illustration they are shown to be distributed irregularly, but in many instances of acute general tuberculosis the tubercles are arranged in groups or irregular circles, following more exactly the arrangement of the vascular supply. Fig. 2 shows the section of a kidney in its long axes, the pelvis being laid open. The cortex is invaded by a great number of miliary tubercles forming clots and streaks. In some parts the tuberculous masses have joined together and have softened. The mucous membrane of the pelvis and calices is much thickened and at the lower end of the section two cavities have formed which are filled with tuberculous débris. (After Rayer) The regular arrangement is seen in a few cases, but in some of those which have come under my observation the tubercles have been distributed without any very evident relationship to the arterial supply, while in other instances the infective process

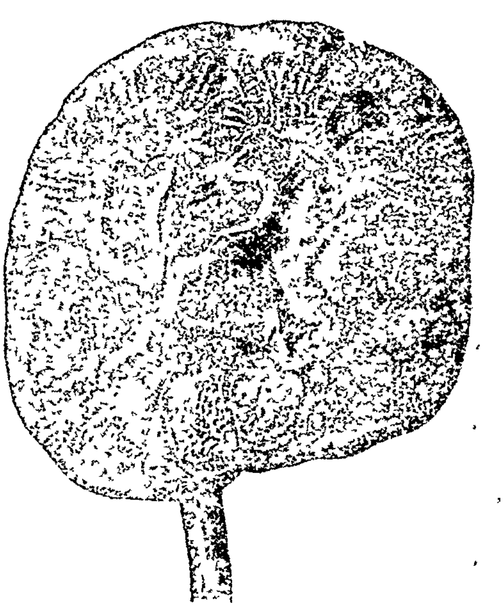
External appearance of a tuberculous kidney.

FIG 2.



Section of a tuberculous kidney

has appeared as if limited to an area supplied by a single branch of the renal artery Borrel in his investigation into the etiology of renal tuberculosis found it necessary, in order to produce the disease, to inject infective matter into the aorta of animals, as when it was introduced into the veins even pure cultures of tubercle bacilli failed to pass through the lungs As regards etiology he concludes that there are two forms of tuberculous disease, primary renal tuberculosis, where the virus is by some means introduced into the arterial current and in which the tuberculosis rapidly follows the inoculation, and secondary renal tuberculosis, which after inoculation takes two or three weeks to develop The invasion taking place through the lymphatics leads to the formation of a caseous nodule and the production of caseous nephritis Borrel calls this "granular tuberculosis of the kidney" There is no precise localisation, the tuberculous material occupying any portion of the parenchyma of the organ In both forms of the disease the tubercle is clearly a connective tissue formation, the renal epithelium taking little or no part in the structure of the new growth The same view is held by Virchow and Metchnikoff

A considerable amount of labour has been devoted to the study of the origin of the various elements which come to form the miliary tubercle In miliary tuberculosis the small tubercles consist of altered portions of the kidney connective tissue appearing in small circumscribed areas infiltrated by leucocytes which are at first clear in colour and tolerably well defined The irritative action of the bacilli induces these early tissue changes The connective tissue cells become swollen and undergo mitotic division, and because of their large size they have been called "epithelioid cells" At the periphery lymphocytes appear and they gradually increase in number The toxic action of the bacilli is first seen in the centre of the focus where the "epithelioid cells" become hyaline and their outline indistinct Ultimately the cells become fused into a homogeneous mass which subsequently degenerates, or the "epithelioid cells" may by proliferation of their nuclei without segmentation of their protoplasm come to form the so-called "giant cell" which was at one time considered to be characteristic of tubercle At the same time the epithelium of the tubules undergoes fatty metamorphosis, the tubules become compressed by the abundant connective tissue formation around them, and the infiltrated leucocytes and epithelium swell up and undergo caseous necrosis, so that ultimately, should time permit, the whole infected area becomes disorganised This degenerative change begins at the centre of the tubercle and extends towards the periphery, where the micro organisms are most abundant The degenerative changes are probably partly due to thrombosis of the capillaries as a consequence of the action of the toxin upon their walls, but the necrosis and caseation are doubtless also the direct result of the bacillary products In some parts these little tuberculous masses coalesce and unitedly form patches of considerable size, which in the first instance are usually situated at the union *of the cortex and medulla*, *but* on account of the remarkable tendency which tuberculous inflammation has to spread they may ultimately involve a considerable portion of the kidney. In such masses blood vessels larger than capillaries become occluded by thrombi and as a consequence further necrosis ensues In this form of renal tuberculosis the disease is generally at first confined to the parenchyma of the kidney and does not immediately extend to the lower urinary tract

Miliary renal tuberculosis is always associated with tuberculous disease in other parts and is a disease which attacks children more frequently than adults It may be preceded by tuberculous formations in any part of the body, but the most common precursor is phthisis pulmonalis Next in order of frequency comes tuberculous meningitis, while in some instances lymphatic glands, joints, or bones have been found to contain the primary focus, and only in a few cases the prostate gland or the bladder have been named as the site of origin of the disease

The discovery of the presence of renal miliary tuberculosis is frequently made for the first time after the death of the patient, and as the lesion does not give rise to any distinctive symptoms the disease is one which is to be inferred from the general circumstances of the case rather than definitely diagnosed; besides, it is one for which nothing can be done surgically

(*b*) Tuberculous embolism of the arteries There is another method by which the kidney may be infected In place of conveying individual bacilli or small groups of bacilli the blood stream may carry an infected thrombus to the kidney, the artery in which it becomes impacted is closed, and the tuberculous virus is more or less disseminated over the area supplied by the blood vessels Hence we find considerable wedge shaped areas of tuberculous disease in the kidney with little or no evidence of involvement of the pelvis or ureter. These masses may, however, break down and lead to a widely disseminated lesion, or, as is not uncommonly the case tuberculous material may caseate or even become encysted (Fig. 4)

FIG 3

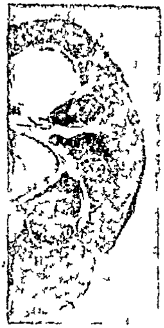


FIG 4

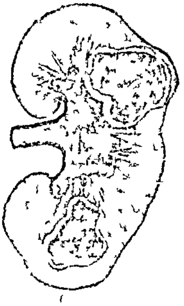


(Fig 3 shows the longitudinal section of a kidney in which tuberculous disease is seen in different stages In the peripheral portion of the cortex and extending towards the medulla there are numerous tuberculous infarctions in some of which caseation has taken place, while in others cavities have formed In the medullary area there are five large cavities, all of which contained caseous matter and tuberculous débris, but none of them communicated with the pelvis, and the urinary tract was free from disease Fig 4 shows the section of a kidney containing two distinct isolated foci of tuberculous disease limited to the medulla and cortex of the organ, the pelvis being free from disease)

The encysted form of the disease is of great importance to the surgeon, being in many instances amenable to operative treatment Generally the disease is unilateral and involves only a portion of the kidney substance, although it may have more than one focus While caseous nephritis arises in most instances as a consequence of tuberculous thrombosis it may be mentioned that in a few cases the renal lesion may be the result of an extension of the tuberculous process from the pelvis of the kidney to the parenchyma through the lymphatics or along the lumina of the uriniferous tubules

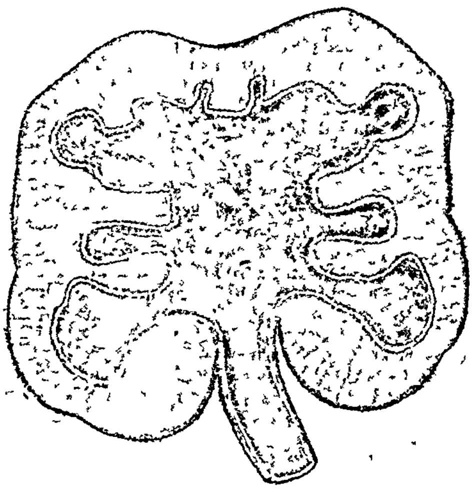
CASE 4 *Tuberculosis limited to the right kidney, compensatory hypertrophy of the left kidney, tubercle bacillus, pus and albumin in the urine from the right kidney only, nephrectomy, cure* —A man, aged 22 years, consulted me in July, 1897 At that time he complained of pain in the right lumbar region almost constantly present, but never very severe. On inquiring into the history of the case it appeared that the first departure from health was noticed three years previously At that time he complained of frequent micturition, requiring to rise six or eight times during the night The urine was copious, pale in colour, of low specific gravity, and contained no deposit Polyuria and frequent micturition were the only symptoms during the first six months, at that time, however, pain was complained of and in the urine the patient noticed on one or two occasions a small quantity of blood He never passed gravel or stone Six months previously (February, 1897) he had noticed a white deposit which, according to his description, appeared to be pus, at the same time pain developed in the right lumbar region, occasionally accompanied by nausea and sickness The appetite gradually became impaired and the patient was much troubled with sleeplessness and he gradually lost weight When first examined he weighed 10 st, he was 5 ft 10 in in height, thin, anæmic, and seemed highly nervous and anxious as to his condition organs were normal, but there was slight enlargement of the liver and spleen. Both kidneys were distinctly felt on palpation and were found to be enlarged; the right was irregular in form, the lower extremity being rounded while the upper was more pointed, giving to the organ somewhat the form of a pear; the left kidney was uniformly enlarged. The urine was pale in colour; its specific gravity was 1008; it was cloudy, and on standing threw down a moderate deposit of mucus and pus; it contained no crystalline deposit; there was a small trace of albumin but no blood. On four examinations out of six tubercle bacilli were found. Examination of the bladder with the cystoscope showed it to be free from disease, with the exception that the orifice of the right ureter protruded and the mucous membrane covering it was deeply injected. Catheterisation of the ureters showed that all of the pus, the albumin, and the tubercle bacilli came from the right kidney; that from the left kidney was normal with the exception of being low in specific gravity. The conclusion come to was that the right kidney was the seat of tuberculous disease while the left had undergone compensatory hypertrophy. The right kidney was excised and was found to contain two considerable tuberculous foci, but the pelvis was not involved in the disease (Fig. 4). The patient made a good recovery and reported himself well in January, 1899.

In the early stage the lesion is limited to the substance of the kidney, the virus being conveyed in the blood stream only, but in the later developments the advancing tuberculous process comes gradually to be carried forward through other channels, unless a conservative inflammatory action closes the lymphatics and prevents extension. If the caseous material breaks down rapid destruction of the organ may result, so that in one specimen renal tuberculosis in all its stages may be seen. The order of infection can, however, be generally determined by careful observation.

In tuberculous pyonephritis infection may take place in various ways. The primary focus may be in the kidney substance, and in such cases the parenchyma may be greatly destroyed before the pelvis is seriously involved and the walls of the ureter thickened sufficiently to cause much or any obstruction to the escape of urine. While the organ may be enlarged by the caseous deposits which have come to occupy its substance the increase in bulk is seldom due to a retention of urine or of tuberculous débris in the pelvis. The ureter is patent and the degenerated tuberculous material is allowed to escape into the bladder to be discharged with the urine. So long as this freedom exists there is no pyonephrosis, but if the ureter becomes blocked by tuberculous thickening of its walls, by impaction of masses of débris, by cicatricial stenosis, or by twisting of the ureter, the secretion is then dammed back and then sudden and rapid changes take place in the morbid condition and in the clinical aspect of the case. The secretion of the kidney and the tuberculous débris, which is probably up till the present free from sepsis, is now very liable to contamination by pyogenic organisms, and within a few hours the whole clinical features of the case may become completely altered. It is easy to understand how large collections of fluid, tuberculous débris mixed with urine, should become contaminated by pyogenic organisms and large renal abscesses or pyonephrosis result. On the other hand, it is undoubted that they may remain aseptic for long periods.

Primary tuberculosis of the pelvis of the kidney is less common than secondary infection of that part. The principal seat of the disease is at the apices of the papillæ, in the calices, or in the pelvis, and from hence, partly by the blood stream and partly by the lymphatic channels, the material virus is carried within the substance of the kidney. The primary focus becomes occupied first by miliary tubercles and subsequently by caseous masses. In the course of a few weeks or months these masses form an irregular softened area, which by progressive peripheral infiltration spreads inwards. At the same time by infection through the blood-vessels and lymphatics, now, and to the naked eye, apparently independent nodules develop in the tissue around, while in the more remote parts of the kidney and in the mucous membrane of the pelvis fresh eruptions of opaque white nodules appear. In recent cases these diminish in size and number the more distant they are from the primary focus, but when the disease is of long standing the individual nodules cannot be distinguished. The constructive process which has just been described is rapidly followed by a destructive one. The tuberculous nodules, having attained a certain size, undergo caseous necrosis, break down, and when in the pelvis of the kidney they become replaced by a tuberculous ulcerating surface, or if within the renal parenchyma they are transformed into irregularly globular cavities. These as they enlarge become elongated and assume a pyriform shape and approaching the cavity of the renal pelvis rupture into it. As the destructive process extends from within outwards greater and greater portions of the renal substance become involved, until finally the whole of the medulla and a large portion of the cortex may be destroyed. This leads to the formation of a large cavity (Fig. 5). But besides the encroachment on the renal tissue by tuberculous disease dilatation and sacculation of the organ may be caused by a blocking of the ureter, ultimately producing a tuberculous pyonephrosis which sometimes, when the other kidney is free from disease, destroys all vestige of urine-secreting tissue. Should only one organ be involved the kidney may, by a drying-up of the contents of the pyonephrosis, become converted into a shrivelled, putty-like mass (Fig. 7). In old cases calcification may occur and a hard mass may form which is liable to be mistaken for a calculus.

FIG. 5.



Specimen of a tuberculous single kidney. The pelvis and calices are greatly dilated and the mucous surface is ulcerated and thickened. The parenchyma of the organ is not diminished in amount but rather increased from compensatory hypertrophy.

CASE 5. *Bilateral renal tuberculosis without involvement of the urinary tract; the right kidney completely destroyed and caseous; the left kidney enlarged and occupied by tuberculous pyonephrosis; tuberculous disease of the sacrum, nephrotomy; death 18 days after from suppression of urine.*—A woman, aged 33 years, was admitted into the Glasgow Royal Infirmary on March 9th, 1899. She consulted me in private six weeks previously to admission, when she was advised to come into the ward as early as possible. She was a well-nourished woman, but she complained of symptoms of dyspepsia and of occasional attacks of severe pain in the region of the left kidney, generally limited to the lumbar region but occasionally extending down the thighs. The patient also complained of frequent micturition and discomfort in the bladder, which, however, subsided immediately the bladder was emptied. There was no history of hæmaturia, but the patient observed on many occasions a whitish deposit which from her description was evidently pus. When the patient was first seen a complete and systematic examination was made, and I concluded that she was suffering from a large pyonephrosis of the left kidney. The right kidney could be felt and it appeared to be normal in size and in situation, and the patient stated that as far as she was aware it had not caused her any trouble. The urine had a specific gravity of 1016 with an acid reaction; it contained a trace of albumin, a few red blood corpuscles, and pus was deposited on standing equal to about 2 per cent.; no crystalline deposit was thrown down, no tubercle bacilli were discovered, and there was no sugar. The heart, the lungs, and the liver and spleen were normal. The left kidney was so enlarged as to occupy the whole space between the costal margins and the crest of the ilium, and it extended as far forward as to within one and a half inches of the nipple line The swelling was dull on percussion and slightly fluctuant and the organ was distinctly tender on palpation The patient was advised to come into the Royal Infirmary at once, but this she failed to do until six weeks later Complete suppression of urine occurred on March 8th, associated with rigors elevation of temperature and profuse sweating The symptoms were so urgent that the patient was sent in on the evening of the 9th, and on the following morning it was found necessary to perform nephrotomy, when one and a half pints of pus and urine were evacuated The patient stated that she had suffered from pain in the left side for 15 years, but that it had been specially severe during the past three years After the operation the left kidney continued to discharge a considerable quantity of urine which for the first three days was mixed with pus, but after that time the pus diminished considerably, no urine, however passed from the urethra and on passing a catheter the bladder was found to be empty, the inference being that no urine was being secreted by the right kidney During the first 15 days urine in considerable quantity drained away from the left kidney, but on March 25th it was observed that although the drainage tube was still communicating with the cavity in the kidney almost no urine escaped The patient complained of an increased amount of pain sickness and diarrhœa Diuretics produced no effect and she died three days after from suppression of urine

Post mortem the left kidney was found to be fully three times the normal size and a large cavity was discovered occupying the pelvis and parenchyma of the organ, but on making allowance for the displacement of the substance of the kidney by disease the secreting tissue remaining appeared to be much in excess of what is found in the normal kidney, probably due to a compensatory hypertrophy (Fig 6) The right kidney was simply a multilocular cyst of about the size of a normal kidney There was no vestige of renal tissue left and the loculi contained soft white caseous material (Fig 7) A careful examination was made of the ureters and the bladder and they were found to be free from disease A caseous mass was found over the front of the sacrum and there was caries of both sacro iliac synchondroses

FIG 6

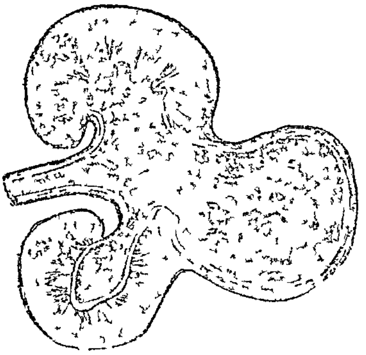


Fig 6 shows a section of the left kidney The pelvis and the middle third of the organ are occupied by a large tuberculous pyonephrosis and a large sac protrudes considerably beyond the outer border The upper and lower thirds of the kidney are not much involved in the disease (Royal Infirmary Museum Series VII No M 19)

Judging from the morbid appearances and the history of the case it is evident that the right kidney was destroyed at a very early date without causing the patient much suffering She could not remember having had aching in the right renal region although on the left side she had during a period of 15 years more or less intense pain sometimes amounting to anguish At the same time there must have been a very sudden and complete blocking of the right ureter, as there was no evidence of the kidney being distended or of the infection having spread downwards Coincident with or following the destructive process in the right kidney the left kidney underwent a compensatory hypertrophy, but at a later period infected matter must have been conveyed to it by the blood, probably in the form of a tuberculous embolism The tuberculous disease in the left kidney was not very destructive although of old standing

FIG 7

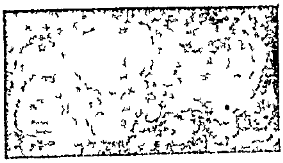

Fig 7 —The whole kidney has been destroyed the capsule and a few fibrous septa alone remain to represent the organ which has been replaced by caseous masses (Royal Infirmary Museum Series VII No. M 20.)

(To be continued)

EPISTAXIS FROM THE ETHMOIDAL VEINS

BY A BROWN KELLY, B Sc, M B GLASG,
SURGEON FOR DISEASES OF THE THROAT NOSE, AND EAR TO THE VICTORIA INFIRMARY, GLASGOW

IT is generally admitted that spontaneous epistaxis usually originates from the lower and anterior part of the cartilaginous septum Hæmorrhages from this source, however, are rarely so profuse as to be dangerous, and they give trouble rather on account of their recurrence In another variety of bleeding from the nose—viz, that observed in certain constitutional diseases, as in hæmophilia and purpura—the blood escapes from numerous points of the mucous membrane In a third class may be placed the hæmorrhages coming from neither of the sources mentioned The site of the bleeding in these cases owing to the fast-flowing stream, as a rule remains undiscovered, this has been traced however, to the inferior turbinate, to veins in the posterior part of the nose by Schmidt,[1] and to an artery on the floor anteriorly by Rosenberg[2] Several cases of epistaxis have come under my notice in which the blood descended from the upper and anterior part of the nasal cavity The anatomical relations of the vessels in this situation lead me to believe that they are not infrequently the source of severe hæmorrhage The following cases—for permission to publish which my thanks are due to Mr R H Parry, Dr A Napier, and Dr E Duncan—are reported with the object of directing attention to this hitherto unrecognised origin

CASE 1 —A man aged 34 years was awakened one morning by bleeding from the left nostril which continued for a quarter of an hour In the evening it set in again, lasted two hours and was followed by recurrence at short intervals throughout the night Various measures of relief were adopted by the three medical men summoned but with only temporary benefit On the next afternoon there was again epistaxis for two hours after which he was admitted in a weak condition to Mr R H Parry s ward in the Victoria Infirmary, Glasgow A little later in consequence of a further loss of blood the patient became unconscious During the next three weeks he had frequent epistaxis which was always promptly checked by plugging I examined him during one attack and found the blood coming from above the middle turbinate but owing to the profuse flow the exact seat of origin could not be determined In order to reach this, on a subsequent occasion part of the middle turbinate was removed I never happened, however, to be present at another bleeding, although he tried to bring on an attack during my visits by running, standing on his head, &c. Since his dismissal from the infirmary, over three years ago, there has been no recurrence.

---

[2] Heymann s Handbuch der Laryngologie und Rhinologie, Band III, S 710

CASE 2.—A man, aged 28 years, lightly built, healthy, and with no hæmorrhagic tendency, first had epistaxis on stooping to pick up something from the floor. The blood dropped from the right nostril but soon ceased. Next forenoon, while walking through his office, the bleeding suddenly re-commenced and he lost several ounces. During the following week there was frequent epistaxis, 24 hours being the longest period of cessation. There were no premonitory symptoms before the onset or subsequent attacks, but he felt irritation at a spot which from his description appeared to be in the neighbourhood of the anterior end of the right middle turbinate. His medical attendant tried various local and constitutional remedies, but found plugging the only means of even partially checking the hæmorrhage. On the ninth day, when I saw the patient for the first time, he was very weak and could not sit up in bed unaided. On removing the plugs the only point that appeared to have bled lately was on the right side of the cartilaginous septum below. This region was packed, and I was leaving the room when the patient began to spit blood. In the rhinoscopic mirror the stream could now be traced to the right posterior naris. The anterior plug was removed and fresh gauze was packed around the middle turbinate. Three days later this was renewed. The exact situation of the bleeding point in this case was not discovered, but after the upper part of the nasal cavity had been twice packed no further hæmorrhage took place.

CASE 3.—A woman, aged 44 years (who was seen in Dr. Napier's ward), stated that she had had epistaxis for the first time in 1890. She then lost a large amount of blood from both sides of the nose and the resulting debility kept her in bed for several weeks. The next attack was in 1896 and from the left side. The flow was very profuse at intervals for about five days, during two of which she was unconscious. After recovering from this attack she was well and doing her household work until four months before admission to the hospital, when in consequence of oppressed breathing she had to take to her bed. The third attack, during which I saw her, occurred in October, 1899. Bleeding began from the right nostril while she was lying quietly in bed, and according to her own statement she lost about a pint. At night there was another large hæmorrhage, after which she was brought to the Victoria Infirmary, Glasgow. During the first four days of residence in the infirmary she had three bleedings, during which she lost respectively 10, five, and 20 ounces. While the last hæmorrhage was going on I examined her and found the stream descending in pulse-like waves over the anterior part of the septum on the right side; the source was above the middle turbinate and out of view. A strip of gauze packed between this body and the septum at once checked the flow. Two days later when the gauze was being changed a slight recurrence took place, but there has been none since. The patient had a ventricular systolic murmur and the second sound was accentuated, but there was no cardiac enlargement. Epistaxis was preceded by a feeling of heaviness in the right half of the head.

CASE 4.—A man, aged 46 years, was admitted to Dr. E. Duncan's ward in the Victoria Infirmary, Glasgow, on Nov. 3rd, 1899, on account of epistaxis. The bleeding had commenced nine days previously while he was washing his face. There were several recurrences, the loss of blood on each occasion averaging from two to three ounces. When I saw him on the day after admission, although the right side of the nose was plugged anteriorly and posteriorly, blood was oozing through the packing. This was removed and the clots were syringed out. The blood could then be seen flowing down the septum from above the anterior end of the right middle turbinate. A strip of gauze firmly packed in this situation stopped the bleeding. A fresh plug was inserted next day and removed two days later, and there has been no subsequent recurrence. The patient was plethoric, but examination of his heart, lungs, liver, and urine revealed nothing abnormal. Shortly after leaving the hospital, however, albuminuria set in.

In Case 1, Case 3, and Case 4 the bleeding occurred above the anterior end of the middle turbinate. In Case 2 the patient was too weak to sit up and the blood flowed backwards into the naso-pharynx and could not be traced to its source. It is probable, however, that in this patient also the bleeding point was above the middle turbinate, for a plug inserted here checked the hæmorrhage. In addition it was observed in Case 3 and Case 4 that the stream descended over the septum. It is evident, therefore, that the ruptured vessel was on the roof or on the septum above the anterior end of the middle turbinate. This situation corresponds with that of the anterior ethmoidal vessels. The circumstances under which the bleeding commenced in the cases above reported suggest venous engorgement rather than arterial pressure as the cause of rupture; for at the onset the first patient was asleep, the second was stooping, the third was lying quietly in bed, and the fourth was washing his face. The anatomical relations also seem to point to the veins as the source of the hæmorrhage.
